Soft Ferrites

Introduction

THE NATURE OF SOFT FERRITES

Composition

Ferrites are dark grey or black ceramic materials. They are very hard, brittle and chemically inert. Most modern magnetically soft ferrites have a cubic (spinel) structure.

The general composition of such ferrites is MeFe_2O_4 where Me represents one or several of the divalent transition metals such as manganese (Mn), zinc (Zn), nickel (Ni), cobalt (Co), copper (Cu), iron (Fe) or magnesium (Mg).

The most popular combinations are manganese and zinc (MnZn) or nickel and zinc (NiZn). These compounds exhibit good magnetic properties below a certain temperature, called the Curie Temperature (T_C). They can easily be magnetized and have a rather high intrinsic resistivity. These materials can be used up to very high frequencies without laminating, as is the normal requirement for magnetic metals.

NiZn ferrites have a very high resistivity and are most suitable for frequencies over 1 MHz, however, MnZn ferrites exhibit higher permeability (μ_i) and saturation induction levels (B_s) and are suitable up to 3 MHz.

For certain special applications, single crystal ferrites can be produced, but the majority of ferrites are manufactured as polycrystalline ceramics.

Manufacturing process

The following description of the production process is typical for the manufacture of our range of soft ferrites, which is marketed under the trade name 'Ferroxcube'.

RAW MATERIALS

The raw materials used are oxides or carbonates of the constituent metals. The final material grade determines the necessary purity of the raw materials used, which, as a result is reflected in the overall cost.

PROPORTIONS OF THE COMPOSITION

The base materials are weighed into the correct proportions required for the final composition.

MIXING

The powders are mixed to obtain a uniform distribution of the components.

PRE-SINTERING

The mixed oxides are calcined at approximately 1000 °C. A solid state reaction takes place between the constituents and, at this stage, a ferrite is already formed.

Pre-sintering is not essential but provides a number of advantages during the remainder of the production process.

MILLING AND GRANULATION

The pre-sintered material is milled to a specific particle size, usually in a slurry with water. A small proportion of organic binder is added, and then the slurry is spray-dried to form granules suitable for the forming process.

FORMING

Most ferrite parts are formed by pressing. The granules are poured into a suitable die and then compressed. The organic binder acts in a similar way to an adhesive and a so-called 'green' product is formed. It is still very fragile and requires sintering to obtain the final ferrite properties.

For some products, for example, long rods or tubes, the material is mixed into a dough and extruded through a suitable orifice. The final products are cut to the required length before or after sintering.

SINTERING

The 'green' cores are loaded on refractory plates and sintered at a temperature between 1150 °C and 1300 °C depending on the ferrite grade. A linear shrinkage of up to 20% (50% in volume) takes place. The sintering may take place in tunnel kilns having a fixed temperature and atmosphere distribution or in box kilns where temperature and atmosphere are computer controlled as a function of time. The latter type is more suitable for high grade ferrites which require a very stringent control in conditions.

FINISHING

After sintering, the ferrite core has the required magnetic properties. It can easily be magnetized by an external field (see Fig.2), exhibiting the well-known hysteresis effect (see Fig.1). Dimensions are typically within 2% of nominal due to 10- 20% shrinkage. If this tolerance is too large or if some surfaces require a smooth finish (e.g. mating faces between core halves) a grinding operation is necessary. Usually diamond-coated wheels are used. For high permeability materials, very smooth, lapped, mating surfaces are required. If an air-gap is required in the application, it may be provided by centre pole grinding.

Soft Ferrites

Introduction

Magnetism in ferrites

A sintered ferrite consists of small crystals, typically 10 to 20 μm in dimension. Domains exist within these crystals (Weiss domains) in which the molecular magnets are already aligned (ferrimagnetism). When a driving magnetic field (H) is applied to the material the domains progressively align with it, as shown in Fig.2.

During this magnetization process energy barriers have to be overcome. Therefore the magnetization will always lag behind the field. A so-called hysteresis loop (see Fig.1) is the result.

If the resistance against magnetization is small, a large induced flux will result at a given magnetic field. The value of the permeability is high. The shape of the hysteresis loop also has a marked influence on other properties, for example power losses.

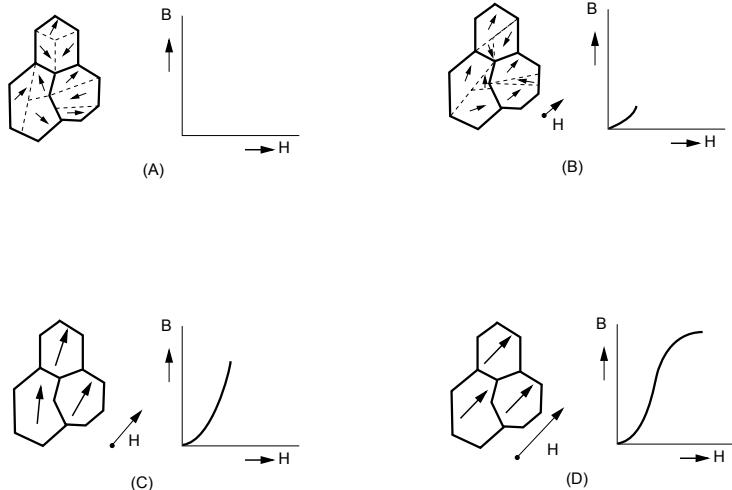

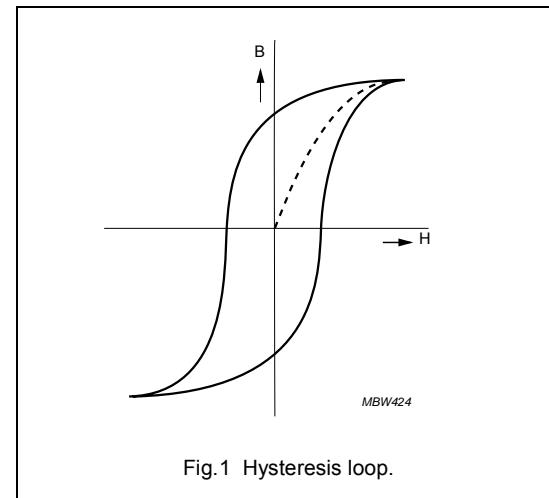

Fig.2 Alignment of domains.

Soft Ferrites**Introduction****EXPLANATION OF TERMS AND FORMULAE****Symbols and units**

SYMBOL	DESCRIPTION	UNIT
A_e	effective cross-sectional area of a core	mm ²
A_{\min}	minimum cross-sectional area of a core	mm ²

$\Sigma(I/A)$	core factor (C1)	mm ⁻¹

Soft Ferrites

Introduction

Definition of terms

PERMEABILITY

When a magnetic field is applied to a soft magnetic material, the resulting flux density is composed of that of free space plus the contribution of the aligned domains.

$$B = \mu_0 H + J \quad \text{or} \quad B = \mu_0(H + M) \quad (1)$$

where $\mu_0 = 4\pi \cdot 10^{-7}$ H/m, J is the magnetic polarization and M is the magnetization.

The ratio of flux density and applied field is called absolute permeability.

$$\frac{B}{H} = \mu_0 \left(1 + \frac{M}{H}\right) = \mu_{\text{absolute}} \quad (2)$$

It is usual to express this absolute permeability as the product of the magnetic constant of free space and the relative permeability (μ_r).

$$\frac{B}{H} = \mu_0 \mu_r \quad (3)$$

Since there are several versions of μ_r depending on conditions the index 'r' is generally removed and replaced by the applicable symbol e.g. μ_i , μ_a , μ_Δ etc.

INITIAL PERMEABILITY

The initial permeability is measured in a closed magnetic circuit (ring core) using a very low field strength.

$$\mu_i = \frac{1}{\mu_0} \times \frac{\Delta B}{\Delta H} \quad (\Delta H \rightarrow 0) \quad (4)$$

Initial permeability is dependent on temperature and frequency.

EFFECTIVE PERMEABILITY

If the air-gap is introduced in a closed magnetic circuit, magnetic polarization becomes more difficult. As a result, the flux density for a given magnetic field strength is lower.

Effective permeability is dependent on the initial permeability of the soft magnetic material and the dimensions of air-gap and circuit.

$$\mu_e = \frac{\mu_i}{1 + \frac{G \times \mu_i}{l_e}} \quad (5)$$

where G is the gap length and l_e is the effective length of magnetic circuit. This simple formula is a good approximation only for small air-gaps. For longer air-gaps some flux will cross the gap outside its normal area (stray flux) causing an increase of the effective permeability.

AMPLITUDE PERMEABILITY

The relationship between higher field strength and flux densities without the presence of a bias field, is given by the amplitude permeability.

$$\mu_a = \frac{1}{\mu_0} \times \frac{\hat{B}}{\hat{H}} \quad (6)$$

Since the BH loop is far from linear, values depend on the applied field peak strength.

INCREMENTAL PERMEABILITY

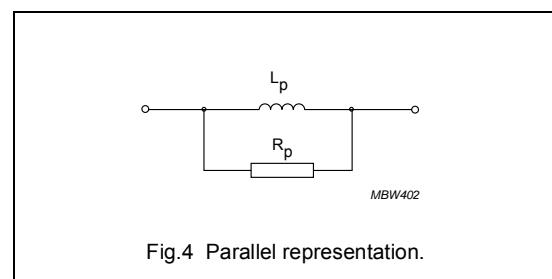

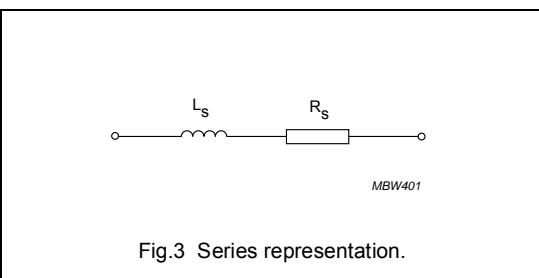

The permeability observed when an alternating magnetic field is superimposed on a static bias field, is called the incremental permeability.

$$\mu_\Delta = \frac{1}{\mu_0} \left[\frac{\Delta B}{\Delta H} \right]_{H_{DC}} \quad (7)$$

If the amplitude of the alternating field is negligibly small, the permeability is then called the reversible permeability (μ_{rev}).

COMPLEX PERMEABILITY

A coil consisting of windings on a soft magnetic core will never be an ideal inductance with a phase angle of 90°. There will always be losses of some kind, causing a phase shift, which can be represented by a series or parallel resistance as shown in Figs 3 and 4.

Soft Ferrites

Introduction

For series representation

$$\bar{Z} = j\omega L_s + R_s \quad (8)$$

and for parallel representation,

$$\bar{Z} = \frac{1}{1/(j\omega L_p) + 1/R_p} \quad (9)$$

the magnetic losses are accounted for if a resistive term is added to the permeability.

$$\mu = \mu'_s - j\mu''_s \quad \text{or} \quad \frac{1}{\mu} = \frac{1}{\mu'_p} - \frac{1}{\mu''_p} \quad (10)$$

The phase shift caused by magnetic losses is given by:

$$\tan \delta_m = \frac{R_s}{\omega L_s} = \frac{\mu''_s}{\mu'_s} \quad \text{or} \quad \frac{\omega L_p}{R_p} = \frac{\mu'_p}{\mu''_p} \quad (11)$$

For calculations on inductors and also to characterize ferrites, the series representations is generally used (μ'_s and μ''_s). In some applications e.g. signal transformers, the use of the parallel representation (μ'_p and μ''_p) is more convenient.

The relationship between the representations is given by:

$$\mu'_p = \mu'_s(1 + \tan \delta^2) \quad \text{and} \quad \mu''_p = \mu''_s \left(1 + \frac{1}{\tan \delta^2}\right) \quad (12)$$

LOSS FACTOR

The magnetic losses which cause the phase shift can be split up into three components:

1. Hysteresis losses
2. Eddy current losses
3. Residual losses.

This gives the formula:

$$\tan \delta_m = \tan \delta_h + \tan \delta_f + \tan \delta_r \quad (13)$$

Figure 5 shows the magnetic losses as a function of frequency.

Hysteresis losses vanish at very low field strengths. Eddy current losses increase with frequency and are negligible at very low frequency. The remaining part is called residual loss. It can be proven that for a gapped magnetic circuit, the following relationship is valid:

$$\frac{(\tan \delta_m)_{gapped}}{\mu_e - 1} = \frac{\tan \delta_m}{\mu_i - 1} \quad (14)$$

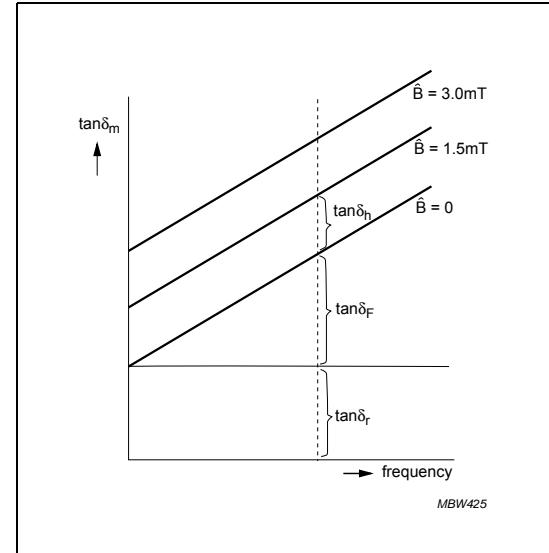

Fig.5 Magnetic losses ($\tan \delta_m$) as a function of frequency.

Since μ_i and μ_e are usually much greater than 1, a good approximation is:

$$\frac{(\tan \delta_m)_{gapped}}{\mu_e} = \frac{\tan \delta_m}{\mu_i} \quad (15)$$

From this formula, the magnetic losses in a gapped circuit can be derived from:

$$(\tan \delta_m)_{gapped} = \frac{\tan \delta_m}{\mu_i} \times \mu_e \quad (16)$$

Normally, the index 'm' is dropped when material properties are discussed:

$$(\tan \delta)_{gapped} = \frac{\tan \delta}{\mu_i} \times \mu_e \quad (17)$$

In material specifications, the loss factor ($\tan \delta / \mu_i$) is used to describe the magnetic losses. These include residual and eddy current losses, but not hysteresis losses.

For inductors used in filter applications, the quality factor (Q) is often used as a measure of performance. It is defined as:

$$Q = \frac{1}{\tan \delta} = \frac{\omega L}{R_{tot}} = \frac{\text{reactance}}{\text{total resistance}} \quad (18)$$

The total resistance includes the effective resistance of the winding at the design frequency.

Soft Ferrites

Introduction

HYSTERESIS MATERIAL CONSTANT

When the flux density of a core is increased, hysteresis losses are more noticeable. Their contribution to the total losses can be obtained by means of two measurements, usually at the induction levels of 1.5 mT and 3 mT. The hysteresis constant is found from:

$$\eta_B = \frac{\Delta \tan \delta_h}{\mu_e \times \Delta B} \quad (19)$$

The hysteresis loss factor for a certain flux density can be calculated using:

$$\frac{\tan \delta_h}{\mu_e} = \eta_B \times \hat{B} \quad (20)$$

This formula is also the IEC definition for the hysteresis constant.

EFFECTIVE CORE DIMENSIONS

To facilitate calculations on a non-uniform soft magnetic cores, a set of effective dimensions is given on each data sheet. These dimensions, effective area (A_e), effective length (l_e) and effective volume (V_e) define a hypothetical ring core which would have the same magnetic properties as the non-uniform core.

The reluctance of the ideal ring core would be:

$$\frac{l_e}{\mu \times A_e} \quad (21)$$

For the non-uniform core shapes, this is usually written as:

$$\frac{1}{\mu_e} \times \sum \frac{l}{A} \quad (22)$$

the core factor divided by the permeability. The inductance of the core can now be calculated using this core factor:

$$L = \frac{\mu_0 \times N^2}{\frac{1}{\mu_e} \times \sum \frac{l}{A}} \quad (23)$$

The effective area is used to calculate the flux density in a core,

for sine wave:

$$\hat{B} = \frac{U \sqrt{2}}{\omega A_e N} = \frac{U}{\pi \sqrt{2} \times f N A_e} \quad (24)$$

for square wave:

$$\hat{B} = \frac{\hat{U}}{4 \times f N A_e} \quad (25)$$

The magnetic field strength (H) is calculated using the effective length (l_e):

$$\hat{H} = \frac{IN\sqrt{2}}{l_e} \quad (26)$$

If the cross-sectional area of a core is non-uniform, there will always be a point where the real cross-section is minimal. This value is known as A_{min} and is used to calculate the maximum flux density in a core. A well designed ferrite core avoids a large difference between A_e and A_{min} . Narrow parts of the core could saturate or cause much higher hysteresis losses.

INDUCTANCE FACTOR (A_L)

To make the calculation of the inductance of a coil easier, the inductance factor, known as the A_L value, is given in each data sheet (in nano Henry). The inductance of the core is defined as:

$$L = N^2 \times A_L \quad (27)$$

The value is calculated using the core factor and the effective permeability:

$$A_L = \frac{\mu_0 \mu_e}{\sum(l/A)} \quad (28)$$

MAGNETIZATION CURVES (H_C , B_R , B_S)

If an alternating field is applied to a soft magnetic material, a hysteresis loop is obtained. For very high field strengths, the maximum attainable flux density is reached. This is known as the saturation flux density (B_s).

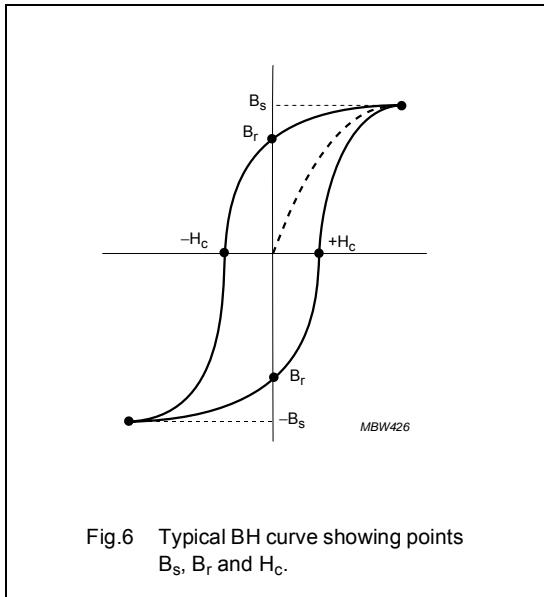

If the field is removed, the material returns to a state where, depending on the material grade, a certain flux density remains. This the remanent flux density (B_r).

This remanent flux returns to zero for a certain negative field strength which is referred to a coercivity (H_c).

These points are clearly shown in Fig.6.

Soft Ferrites

Introduction

So α_F is defined as:

$$\alpha_F = \frac{(\mu_i)_{T2} - (\mu_i)_{T1}}{(\mu_i)_{T1}^2} \times \frac{1}{T_2 - T_1} \quad (31)$$

Or, to be more precise, if the change in permeability over the specified area is rather large:

$$\alpha_F = \frac{(\mu_i)_{T2} - (\mu_i)_{T1}}{(\mu_i)_{T1} \times (\mu_i)_{T2}} \times \frac{1}{T_2 - T_1} \quad (32)$$

The temperature factors for several temperature trajectories of the grades intended for filter applications are given in the material specifications. They offer a simple means to calculate the temperature coefficient of any coil made with these ferrites.

TOTAL HARMONIC DISTORTION (THD)

Harmonic distortion is generated when a sine wave magnetic field H , which is proportional to the current, induces a non-sinusoidal flux density B . This is due to a non linear relation between B and H in the ferrite core of a transformer. Consequently the induced output voltage, which is proportional to the flux density B , is also not a pure sine wave, but somewhat distorted. The periodic voltage signals can be decomposed by writing them as the sum of sine waves with frequencies equal to multiples of the fundamental frequency.

For signals without bias, the THD is defined as the ratio of the square root of the sum of the quadratic amplitudes of the (uneven) higher harmonic voltages and, the amplitude of the fundamental frequency (V_1). It is often sufficient to consider only the strongly dominant third harmonic for the THD. In that case the definition of THD can be simplified to:

$$\text{THD} \approx V_3 / V_1 \text{ or } 20 \times 10^{\log(V_3 / V_1)} [\text{dB}]$$

Introducing an airgap in a core set reduces the THD in the same way as it reduces temperature dependence and magnetic losses, which shows that the THD is not a pure material characteristic. It can be shown by calculation and measurement that THD/μ_{ae} is a real material characteristic. It is a function of flux density (B), frequency (f) and temperature (T), but not of the airgap length in a core set. THD/μ_{ae} is defined as the THD-factor, denoted as THD_F .

The term μ_{ae} stands for effective amplitude permeability of the ferrite material. It is a more general term than the effective permeability μ_e which is only defined for very low flux densities (< 0.25 mT).

Published data of this THD-factor (THD_F) as a function of frequency (f), flux density (B) and temperature (T) can

TEMPERATURE DEPENDENCE OF THE PERMEABILITY

The permeability of a ferrite is a function of temperature. It generally increases with temperature to a maximum value and then drops sharply to a value of 1. The temperature at which this happens is called the Curie temperature (T_c). Typical curves of our grades are given in the material data section.

For filter applications, the temperature dependence of the permeability is a very important parameter. A filter coil should be designed in such a way that the combination it forms with a high quality capacitor results in an LC filter with excellent temperature stability.

The temperature coefficient (TC) of the permeability is given by:

$$TC = \frac{(\mu_i)_{T2} - (\mu_i)_{T1}}{(\mu_i)_{T1}} \times \frac{1}{T_2 - T_1} \quad (29)$$

For a gapped magnetic circuit, the influence of the permeability temperature dependence is reduced by the factor μ_e/μ_i . Hence:

$$TC_{\text{gap}} = \frac{\mu_e}{(\mu_i)_{T1}} \times \frac{(\mu_i)_{T2} - (\mu_i)_{T1}}{(\mu_i)_{T1}^2} \times \left(\frac{1}{T_2 - T_1} \right) \quad (30)$$

$$= \mu_e \times \alpha_F$$

Soft Ferrites

Introduction

directly be used to predict the THD in gapped core sets (THD_C) at the applicable operating conditions off, B and T.

$$\text{THD}_C = \text{THD}_F + 20 \times 10^{\log(\mu_{ae})} [\text{dB}] \quad (33)$$

THD MEASUREMENTS

Measured THD values as well as accuracies depend on the impedances in the measuring circuit used.

Fig.7 shows an equivalent THD test or measuring circuit. In Fig.8 a simplified equivalent circuit is shown with the generated (V_{F3}) and measured third harmonic voltage (V_{M3}).

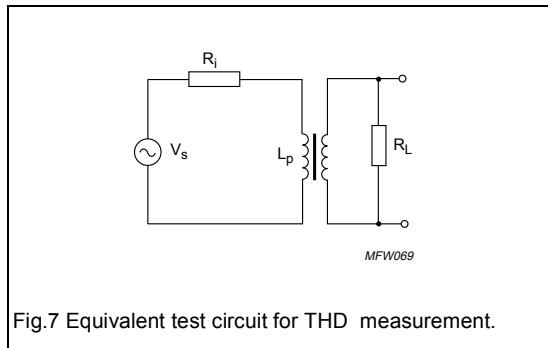

Fig.7 Equivalent test circuit for THD measurement.

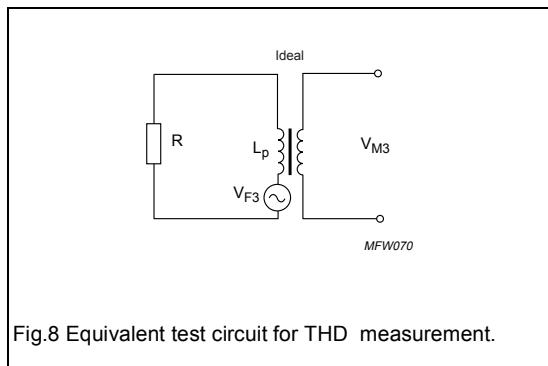

Fig.8 Equivalent test circuit for THD measurement.

The test circuit consists basically of a voltage source and a measuring device capable of measuring the third harmonic voltage or directly the THD. Both devices are often combined in one instrument like e.g. an audio analyzer which is represented by V_s in Fig.7.

R_1 represents the total equivalent resistance in the primary circuit, which consists of the internal resistance of the voltage source, possibly in combination with other resistors in this part of the circuit. L_p is the inductance of

the transformer under test connected to the load resistance R_L .

The generated third harmonic voltage V_{F3} will cause a current flow through the impedances R_1 and R_L , resulting in a voltage drop. These impedances are combined to one equivalent resistance R as shown in Fig.8. This equivalent resistance can be calculated with:

$$R = \frac{R_1 \times R_{L_p}}{R_1 + R_{L_p}} \quad (34)$$

in which R_{L_p} is R_L referred to the primary side:

$$R_{L_p} = \left(\frac{N_p}{N_s} \right)^2 \times R_L \quad (35)$$

Hardly any voltage drop will occur when R is very high compared to the impedance $3\omega L_p$. In that case the measured third harmonic voltage V_{M3} would be equal to the real generated third harmonic V_{F3} multiplied by the transformation ratio N_s/N_p .

The measuring situation would be fully current driven. However in practical situations the resistance R will play a role and V_{F3} can be calculated with equation:

$$V_{F3} = V_{M3} \times \frac{N_p}{N_s} \times \sqrt{1 + (3\omega L_p/R)^2} \quad (36)$$

MEASUREMENT PRECAUTIONS

In general it is advised to check measuring conditions and the test circuit with impedances R and ωL_p in order to keep the circuit correction factor as low as possible. This avoids measuring in non-discriminating ranges (< -80 dB), which may lead to inaccurate or useless results. It is recommended to use low measuring frequencies, preferably < 25 kHz, for several reasons. At high frequencies it will often be difficult to reach the required flux level in the core of the transformer or inductor because of output voltage limitations. The real generated THD by the ferrite core ($\text{THD}_C \approx V_{F3}/V_{F1}$) can be related to the THD which is measured in the circuitry ($\text{THD}_M \approx V_{M3}/V_{M1}$) by knowing that $V_{F1} = V_{M1} \times (N_p/N_s)$. By using equation [36] this relation is as follows :

$$\text{THD}_M = \frac{1}{\sqrt{1 + (3\omega L_p/R)^2}} \times \text{THD}_C = \text{CCF} \times \text{THD}_C \quad (37)$$

The inverse square root term in equation [37] is the circuit correction factor (CCF). To get the measured THD in terms of the factor THD_F , equation [37] must be combined with [33] which gives in units of dB :

$$\text{THD}_M = \text{THD}_F + 20 \times 10^{\log(\mu_{ae} \times \text{CCF})} \quad (38)$$

Soft Ferrites

To make use of equation [38] in practice, the following route can be followed :

The first step is to determine the voltage which will appear across the transformer. This is the voltage V_{Lp} across the inductance L_p in figure 8. If this value is not known from the (test) specification, it can be derived from the source voltage V_s . The relation between the source voltage V_s , the primary voltage V_{Lp} and the secondary voltage V_{RL} is given in equations [39] and [40] :

$$V_{Lp} = V_s \times \frac{j\omega L_p \parallel R_{Lp}}{R_i + (j\omega L_p \parallel R_{Lp})} \quad (39)$$

or

$$V_{Lp} = V_s \times \frac{1}{\sqrt{(1 + R_i/R_{Lp})^2 + (\omega L_p)^2}} \quad (40)$$

and $V_{RL} = (N_s/N_p) \times V_{Lp}$.

The second step is to use Faraday's law for induction to find the flux density B in the transformer. In case the voltage V_{Lp} is a sinusoidal rms voltage, the relation to the peak flux density B_{peak} can be written as :

$$V_{Lp} = \frac{1}{2}\sqrt{2} \cdot \omega \cdot N_1 \cdot A_e \cdot B_{peak} \quad (41)$$

The third step is to use the published curves on THD_F (as e.g. in fig. 4, 5 and 6 for 3E55) to determine the THD_F under the application conditions of f , B and T .

The last step is to use equation [38] to calculate the THD which will be measured and, to check whether this value is in line with the requirement (specification).

Time stability

When a soft magnetic material is given a magnetic, mechanical or thermal disturbance, the permeability rises suddenly and then decreases slowly with time. For a defined time interval, this 'disaccommodation' can be expressed as:

$$D = \frac{\mu_1 - \mu_2}{\mu_1} \quad (42)$$

The decrease of permeability appears to be almost proportional to the logarithm of time. For this reason, IEC has defined a disaccommodation coefficient:

$$d = \frac{\mu_1 - \mu_2}{\mu_1 \times \log(t_2/t_1)} \quad (43)$$

Introduction

Where t_1 and t_2 are time intervals after the disturbance. As with temperature dependence, the influence of disaccommodation on the inductance drift of a coil will be reduced by μ_e/μ_i .

Therefore, a disaccommodation factor D_F is defined:

$$D_F = \frac{d}{\mu_i} = \frac{\mu_1 - \mu_2}{\mu_1^2 \times \log(t_2/t_1)} \quad (44)$$

Usually ferrite cores are magnetically conditioned by means of a saturating alternating field which is gradually reduced to zero. Measurements for our data sheets are taken 10 and 100 minutes after this disturbance. The variability with time of a coil can now easily be predicted by:

$$\frac{L_1 - L_2}{L_1} = \mu_e \times D_F \quad (45)$$

L_1 and L_2 are values at 2 time intervals after a strong disturbance.

RESISTIVITY

Ferrite is a semiconductor with a DC resistivity in the crystallites of the order of $10^{-3} \Omega\text{m}$ for a MnZn type ferrite, and about $30 \Omega\text{m}$ for a NiZn ferrite.

Since there is an isolating layer between the crystals, the bulk resistivity is much higher: 0.1 to $10 \Omega\text{m}$ for MnZn ferrites and 10^4 to $10^6 \Omega\text{m}$ for NiZn and MgZn ferrites.

This resistivity depends on temperature and measuring frequency, which is clearly demonstrated in Tables 1 and 2 which show resistivity as a function of temperature for different materials.

Table 1 Resistivity as a function of temperature of a MnZn-ferrite (3C94)

TEMPERATURE (°C)	RESISTIVITY (Ωm)
-20	≈10
0	≈7
20	≈4
50	≈2
100	≈1

Soft Ferrites

Introduction

Table 2 Resistivity as a function of temperature of a NiZn-ferrite (4C65)

TEMPERATURE (°C)	RESISTIVITY (Ωm)
0	$\approx 5 \cdot 10^7$
20	$\approx 10^7$
60	$\approx 10^6$
100	$\approx 10^5$

At higher frequencies the crystal boundaries are more or less short-circuited by their capacitance and the measured resistivity decreases, as shown in Tables 3 and 4.

Table 3 Resistivity as function of frequency for MnZn ferrites

FREQUENCY (MHz)	RESISTIVITY (Ωm)
0.1	≈ 2
1	≈ 0.5
10	≈ 0.1
100	≈ 0.01

Table 4 Resistivity as function of frequency for NiZn ferrites

FREQUENCY (MHz)	RESISTIVITY (Ωm)
0.1	$\approx 10^5$
1	$\approx 5 \cdot 10^4$
10	$\approx 10^4$
100	$\approx 10^3$

Permittivity

The basic permittivity of all ferrites is of the order of 10. This is valid for MnZn and NiZn materials. The isolating material on the grain boundaries also has a permittivity of approximately 10. However, if the bulk permittivity of a ferrite is measured, very different values of apparent permittivity result. This is caused by the conductivity inside the crystallites. The complicated network of more or less leaky capacitors also shows a strong frequency dependence.

Tables 5 and 6 show the relationship between permittivity and frequency for both MnZn and NiZn ferrites.

Table 5 Permittivity as a function of frequency for MnZn ferrites

FREQUENCY (MHz)	PERMITTIVITY (ϵ_r)
0.1	$\approx 2 \cdot 10^5$
1	$\approx 10^5$
10	$\approx 5 \cdot 10^4$
100	$\approx 10^4$

Table 6 Permittivity as a function of frequency for NiZn ferrites

FREQUENCY (MHz)	PERMITTIVITY (ϵ_r)
0.001	≈ 100
0.01	≈ 50
1	≈ 25
10	≈ 15
100	≈ 12

Soft Ferrites	Quality
QUALITY	
Quality standards	
<p>Our ferrite cores are produced to meet constantly high quality standards. High quality components in mass production require advanced production techniques as well as background knowledge of the product itself. The quality standard is achieved in our ferrite production centres by implementation of a Quality Assurance System based on ISO9001 and our process control is based on SPC techniques.</p> <p>To implement SPC, the production is divided in stages which correspond to production steps or groups of steps. The output of each stage is statistically checked in accordance with MIL STD 414 and 105D.</p> <p>The obtained results are measured against built-in control, warning and rejects levels. If an unfavourable trend is observed in the results from a production stage, corrective and preventive actions are immediately taken. Quality is no longer "inspected-in" but "built-in" by continuous improvement.</p> <p>The system is applicable for the total manufacturing process including,</p> <ul style="list-style-type: none"> • Raw material • Production of process • Finished products. <p>All our production centres are complying with the ISO 9000 quality system.</p>	<p>Different criteria can be agreed upon for customized products. Also PPM agreements with customers are encouraged.</p> <p>Customers may follow the same system to carry out incoming inspections. If the percentage of defects does not exceed the specified level, the probability that the batch will be accepted is high (>90%), but rejection is still possible.</p> <p>If the reject level is much lower than specified, quality complaints will disappear. We aim at very low reject levels to eventually allow any customers to dispose with incoming inspection.</p>
Aspects of quality	
<p>When describing the quality of a product, three aspects must be taken into account:</p> <ul style="list-style-type: none"> • Delivery quality • Fitness for use • Reliability. 	<p>FITNESS FOR USE</p> <p>This is a measure of component quality up to the point where the component has been assembled into the equipment and is quoted in parts per million (PPM). After assembly, the component should function fully. The PPM concept covers the possibility of failures that occur during assembly. It includes line rejects that may occur for any reason.</p> <p>For ferrite cores, co-operation between the component supplier and the customer is a very important aspect. The core is generally a building block for a wound component and many things can go wrong during the assembly process, but the core is not always the problem. A mutual quality control programme can be established to minimize line rejects for a specific application. For some product lines, levels of 30 PPM have already been realized.</p>
DELIVERY QUALITY	
<p>After production, the ferrite components are tested once again for their main characteristics. Tests are conducted in accordance with the guidelines specified by IEC 62044. If a component does not comply with the specification published in this handbook, it is considered to be defective. A sampling system, in accordance with ISO 2859 and ISO 3951 is used. The Acceptable Quality Levels (AQL's) are generally set at 0.25%.</p>	<p>RELIABILITY</p> <p>Ferrite cores are known for their reliability. Once the assembly process has been successfully concluded, no real threats for the life of the ferrite are known.</p> <p>Reliability is mainly governed by the quality of the total assembly of the wound component. Extreme thermal shocks should be avoided.</p>

Soft Ferrites

Environmental aspects

ENVIRONMENTAL ASPECTS OF SOFT FERRITES

Our range of soft ferrites has the general composition MeFe₂O₄ where Me represents one or several of the divalent transition metals such as manganese (Mn), zinc (Zn), nickel (Ni), or magnesium (Mg).

To be more specific, all materials starting with digit 3 are manganese zinc ferrites based on the MnZn composition.

Their general chemical formula is:

Materials starting with digit 4 are nickel zinc ferrites based on the NiZn composition. Their general chemical formula is:

Materials starting with digit 2 are magnesium zinc ferrites based on the MgZn composition. Their general chemical formula is:

General warning rules

- With strong acids, the metals iron, manganese, nickel and zinc may be partially extracted.
- In the event of fire, dust particles with metal oxides will be formed.
- Disposal as industrial waste, depending on local rules and circumstances.

Information about RoHS compliance

Ferroxcube warrants that all products supplied by Ferroxcube do not contain the hazardous substances as described by the directive 2002/95/EC and 2003/11/EC of the European Parliament and the Council of January 27th 2003 and February 6th 2003 "On the restriction of the use of certain hazardous substances in electrical and electronic equipment" (RoHS).

This warranty applies to :

- All bare ferrite cores
- Coated toroids (nylon, epoxy, parylene)
- Encapsulated (plastic) toroids
- Encapsulated (plastic) cable shields
- Coilformers and mounting plates (plastic and metal)
- Metal parts
- Wound ferrites (metal)
- Multi-layer inductors and suppressors (metal)

Soft Ferrites

Ordering information

ORDERING INFORMATION

The products in this handbook are identified by type numbers. All physical and technical properties of the product are expressed by these numbers. They are therefore recommended for both ordering and use on technical drawings and equipment parts lists.

The 11-digit code, used in former editions of this data handbook, also appears on packaging material.

Smallest Packaging Quantities (SPQ) are packs which are ready for shipment to our customers. The information on the barcoded label consists of:

- Technical information:
 - type number
 - 11-digit code number
 - delivery and/or production batch numbers
- Logistic information:
 - 12-digit code number
 - quantity
 - country of origin
 - production week
 - production centre.

The 12-digit code used on the packaging labels, provides full logistic information as well.

During all stages of the production process, data are collected and documented with reference to a unique batch number, which is printed on the packaging label. With this batch number it is always possible to trace the results of process steps afterwards and in the event of customer complaints, this number should always be quoted.

Products are available throughout their lifecycle. A short definition of product status is given in the table "Product status definitions".

Product status definitions

STATUS	INDICATION	DEFINITION
Prototype	prot	These are products that have been made as development samples for the purposes of technical evaluation only. The data for these types is provisional and is subject to change.
Design-in	des	These products are recommended for new designs.
Preferred		These products are recommended for use in current designs and are available via our sales channels.
Support	sup	These products are not recommended for new designs and may not be available through all of our sales channels. Customers are advised to check for availability.

Soft Ferrites

Applications

APPLICATIONS

Introduction

Soft ferrite cores are used wherever effective coupling between an electric current and a magnetic flux is required. They form an essential part of inductors and transformers used in today's main application areas:

- Telecommunications
- Power conversion
- Interference suppression.

The function that the soft magnetic material performs may be one or more of the following:

FILTERING

Filter network with well defined pass-band.

High Q-values for selectivity and good temperature stability.

Material requirements:

- Low losses
- Defined temperature factor to compensate temperature drift of capacitor
- Very stable with time.

Preferred materials: 3D3, 3H3.

INTERFERENCE SUPPRESSION

Unwanted high frequency signals are blocked, wanted signals can pass. With the increasing use of electronic equipment it is of vital importance to suppress interfering signals.

Material requirements:

- High impedance in covered frequency range.

Preferred materials: 3S1, 4S2, 3S3, 3S4, 4C65, 4A11, 4A15, 3B1, 4B1, 3C11, 3E25, 3E5.

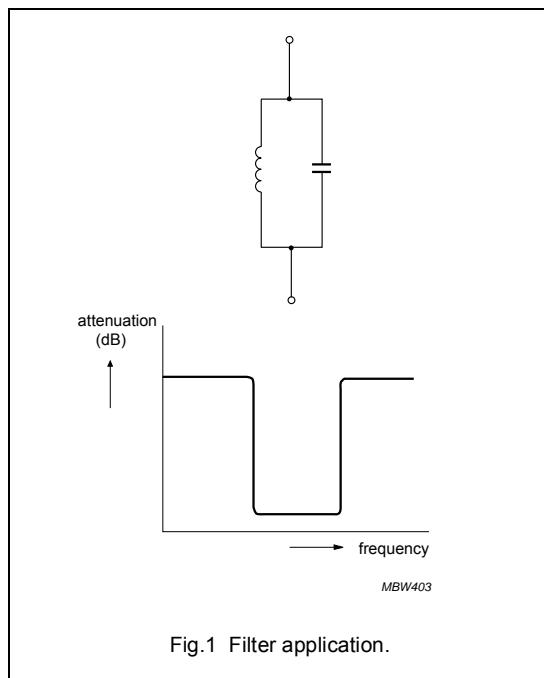

Fig.1 Filter application.

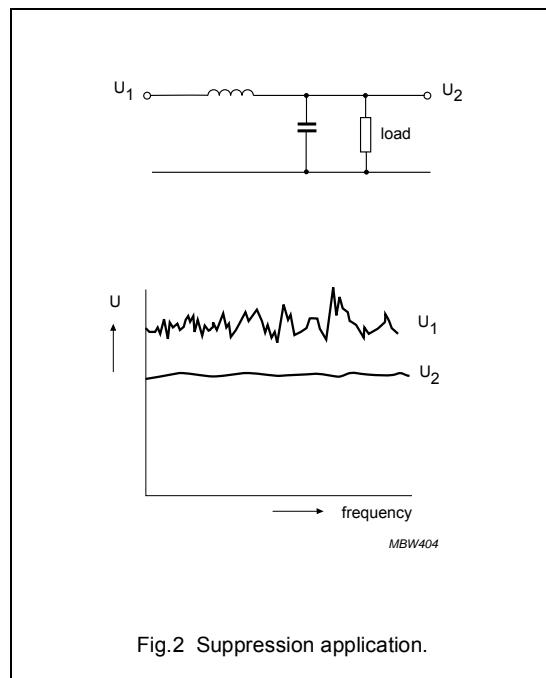

Fig.2 Suppression application.

Soft Ferrites

Applications

DELAYING PULSES

The inductor will block current until saturated. Leading edge is delayed depending on design of magnetic circuit.

Material requirements:

- High permeability (μ_i).

Preferred materials: 3E25, 3E5, 3E6, 3E7, 3E8, 3E9.

STORAGE OF ENERGY

An inductor stores energy and delivers it to the load during the off-time of a Switched Mode Power Supply (SMPS).

Material requirements:

- High saturation level (B_s).

Preferred materials: 3C30, 3C34, 3C90, 3C92, 3C96
2P-iron powder.

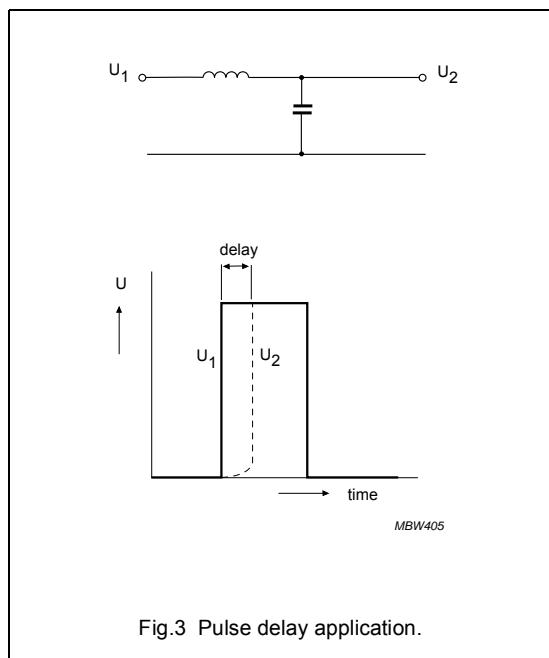

Fig.3 Pulse delay application.

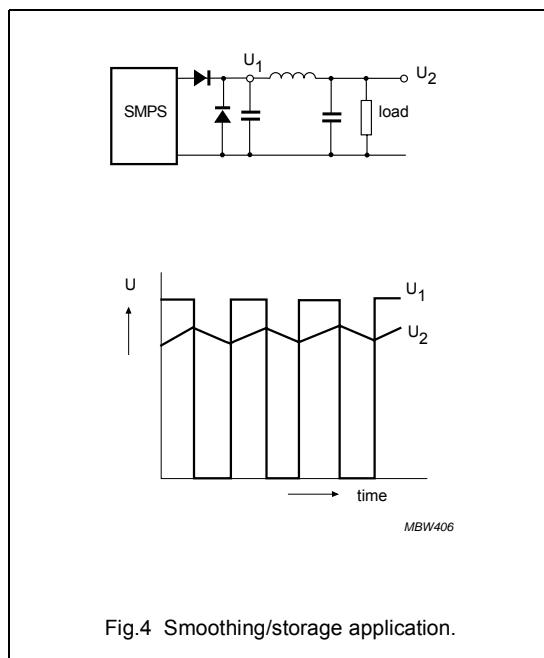

Fig.4 Smoothing/storage application.

Soft Ferrites

Applications

PULSE TRANSFORMERS/GENERAL PURPOSE TRANSFORMERS

Pulse or AC signals are transmitted and if required transformed to a higher or lower voltage level. Also galvanic separation to fulfil safety requirements and impedance matching are provided.

Material requirements:

- High permeability
- Low hysteresis factor for low signal distortion
- Low DC sensitivity.

Preferred materials: 3C81, 3H3, 3E1, 3E4, 3E25, 3E27, 3E28, 3E5, 3E6, 3E7, 3E8.

POWER TRANSFORMERS

A power transformer transmits energy, transforms voltage to the required level and provides galvanic separation (safety).

Material requirements:

- Low power losses
- High saturation (B_s).

Preferred materials: 3C15, 3C30, 3C34, 3C81, 3C90, 3C91, 3C93, 3C94, 3C96, 3F3, 3F35, 3F4, 3F45, 3F5, 4F1.

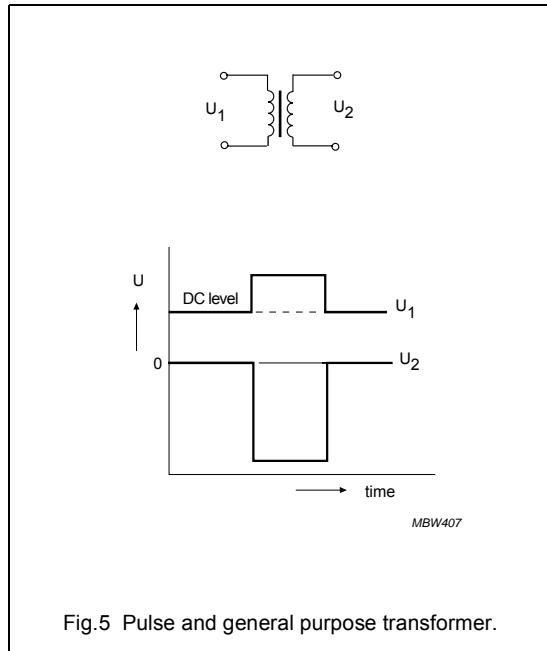

Fig.5 Pulse and general purpose transformer.

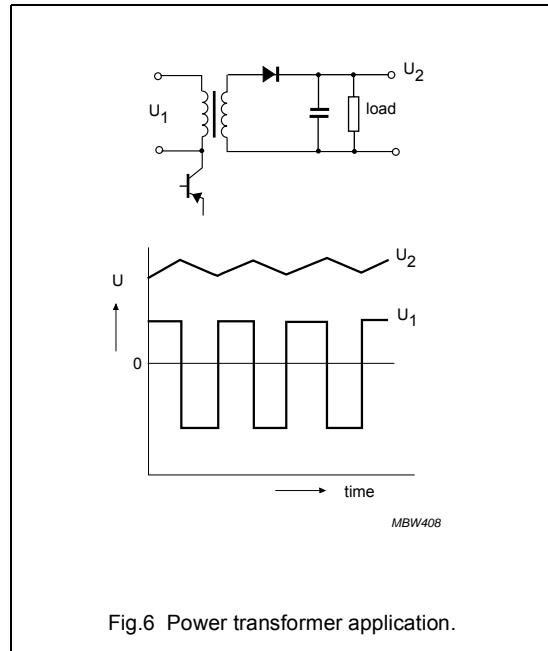

Fig.6 Power transformer application.

Soft Ferrites

Applications

TUNING

LC filters are often used to tune circuits in audio, video and measuring equipment. A very narrow bandwidth is often not wanted.

Material requirements:

- Moderate losses up to high frequency
- Reasonable temperature stability.

Preferred materials: 3D3, 4A11, 4B1, 4C65, 4D2, 4E1.

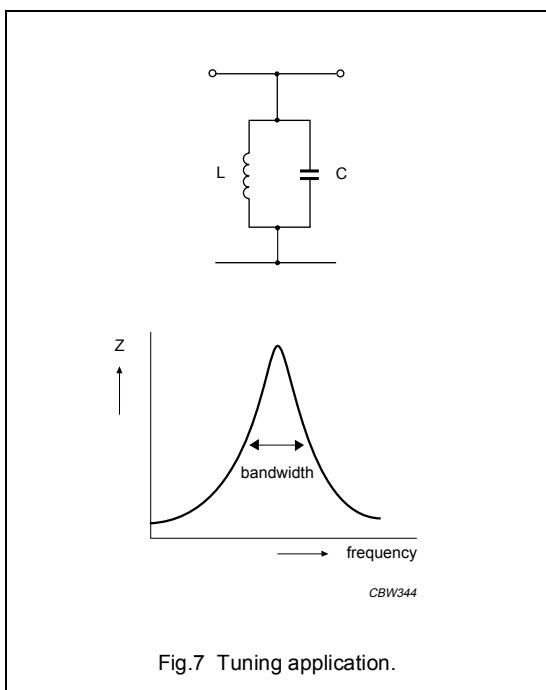

Fig.7 Tuning application.

Soft Ferrites

Applications

Ferrites for Telecommunications

Telecommunications is the first important branch of technology where ferrites have been used on a large scale. Today, against many predictions, it still is an important market for ferrite cores.

Most important applications are in:

- Filter inductors
- Pulse and matching transformers.

FILTER COILS

P cores and RM cores have been developed specially for this application.

The P core is the oldest design. It is still rather popular because the closed shape provides excellent magnetic screening.

RM cores are a later design, leading to a more economic usage of the surface area on the PCB.

For filter coils, the following design parameters are important:

- Precise inductance value
- Low losses, high Q value
- High stability over periods of time
- Fixed temperature dependence.

Q VALUE

The quality factor (Q) of a filter coil should generally be as high as possible. For this reason filter materials such as 3H3 and 3D3 have low magnetic losses in their frequency ranges.

Losses in a coil can be divided into:

- Winding losses, due to the DC resistance of the wire eddy-current losses in the wire, electric losses in insulation
- Core losses, due to hysteresis losses in the core material, eddy-current and residual losses in the core material.

Losses appear as series resistances in the coil:

$$\frac{R_{\text{tot}}}{L} = \frac{R_0}{L} + \frac{R_{\text{ec}}}{L} + \frac{R_d}{L} + \frac{R_h}{L} + \frac{R_{e+r}}{L} \quad (\Omega/H)$$

As a general rule, maximum Q is obtained when the sum of the winding losses is made equal to the sum of the core losses.

DC resistive losses

The DC resistive losses in a winding are given by:

$$\frac{R_0}{L} = \frac{1}{\mu_e} \times \frac{1}{f_{\text{Cu}}} \times \text{constant} \quad (\Omega/H)$$

The space (copper) factor f_{Cu} depends on wire diameter, the amount of insulation and the method of winding.

Eddy-current losses in the winding

Eddy-current losses in a winding are given by:

$$\frac{R_{\text{ec}}}{L} = \frac{C_{w\text{Cu}} V_{\text{Cu}} f^2 d^2}{\mu_e} \quad (\Omega/H)$$

Where $C_{w\text{Cu}}$ is the eddy-current loss factor for the winding and depends on the dimensions of the coil former and core, and V_{Cu} is the volume of conductor in mm^3 , d is the diameter of a single wire in mm.

Dielectric losses

The capacitances associated with the coil are not loss free. They have a loss factor which also increases the effective coil resistance:

$$\frac{R_d}{L} = \omega^3 L C \left(\frac{2}{Q} + \tan \delta_c \right) \quad (\Omega/H)$$

Hysteresis losses

The effective series resistance due to hysteresis losses is calculated from the core hysteresis constant, the peak flux density, the effective permeability and the operating frequency:

$$\frac{R_h}{L} = \omega \eta_B \hat{B} \mu_e \quad (\Omega/H)$$

Eddy-current and residual losses

The effective series resistance due to eddy-current and residual losses is calculated from the loss factor:

$$\frac{R_{e+r}}{L} = \omega \mu_e (\tan \delta / \mu_i) \quad (\Omega/H)$$

Soft Ferrites	Applications
----------------------	---------------------

INDUCTOR DESIGN

The specification of an inductor usually includes:

- The inductance
- Minimum Q at the operating frequency
- Applied voltage
- Maximum size
- Maximum and minimum temperature coefficient
- Range of inductance adjustment.

To satisfy these requirements, the designer has the choice of:

- Core size
- Material grade
- A_L value
- Type of conductor (solid or bunched)
- Type of adjuster.

FREQUENCY, CORE TYPE AND MATERIAL GRADE

The operating frequency is a useful guide to the choice of core type and material.

- Frequencies below 20 kHz:
the highest Q will be obtained with large, high inductance-factor cores of 3H3 material. Winding wire should be solid, with minimum-thickness insulation.
Note: high inductance factors are associated with high temperature coefficients of inductance.
- Frequencies between 20 kHz and 200 kHz:
high Q will generally be obtained with a core also in 3H3. Maximum Q will not necessarily be obtained from the large-size core, particularly at higher frequencies, so the choice of inductance factor is less important. Bunched, stranded conductors should be used to reduce eddy-current losses in the copper. Above 50 kHz, the strands should not be thicker than 0.07 mm.
- Frequencies between 200 kHz and 2 MHz:
use a core of 3D3 material. Bunched conductors of maximum strand diameter 0.04 mm are recommended.

SIGNAL LEVEL

In most applications, the signal voltage is low. It is good practice to keep wherever possible the operating flux density of the core below 1 mT, at which level the effect of hysteresis is usually negligible. At higher flux densities, it may be necessary to allow for some hysteresis loss and inductance change.

The following expression for third harmonic voltage U_3 may be used as a guide to the amount of distortion:

$$\frac{U_3}{U_1} = 0.6 \tan \delta_h$$

For low distortion, materials with small hysteresis loss factors should be used (e.g. 3H3).

DC POLARIZATION

The effect of a steady, superimposed magnetic field due to an external field or a DC component of the winding current is to reduce the inductance value of an inductor. As with other characteristics, the amount of the decrease depends on the value of the effective permeability. The effect can be reduced by using a gapped core or by choosing a lower permeability material.

 A_L VALUE

Since the air gap in ferrite cores can be ground to any length, any value of A_L can be provided within the limits set by the core size. In practice, the range of A_L values has been standardized with values chosen to cover the majority of application requirements.

If a core set is provided with an asymmetrical air gap, this air gap is ground in the upper half. This half is marked with the ferrite grade and A_L value.

For very low A_L values (e.g. 16 to 25) the contribution of the stray inductance will be quite high, resulting in a marked influence of the position of the coil in the core and its number of turns.

Most pre-adjusted cores are provided with an injection-moulded nut for the adjuster.

Continuously variable adjusters can be supplied for pre-adjusted cores of most A_L values. These are specially recommended for filter coils. Maximum adjustment range is 10% to 30%, depending on core type and adjuster.

The A_L factor is the inductance per turn squared (in nH) for a given core:

$$L = N^2 \times A_L \text{ (nH)}$$

The measured A_L value of a core will depend slightly on the coil used for this measurement.

Soft Ferrites

Applications

FERROXCUBE PULSE AND SIGNAL TRANSFORMERS

Pulse and signal transformers, also known as wideband transformers, are frequently used in communication systems, including modern digital networks such as, for example ISDN and XDSL.

They provide impedance matching and DC isolation or transform signal amplitudes. Signal power levels are usually low. In order to transmit analog signals or digital pulses without much distortion, good wideband characteristics are needed.

The principal function of the transformer core is to provide optimum coupling between the windings.

The general equivalent circuit of a signal transformer is shown in Fig.8.

The elements of the circuit depicted in Fig.8 may be defined as follows:

E_s = source voltage

R_s = source resistance

R_w = total winding resistance = $R_1 + R_2$, where R_1 is the primary winding resistance and R_2 is the secondary winding resistance referred to the primary

L = total leakage inductance = the primary inductance with the secondary shorted

L_p = open circuit inductance

R_p = the shunt loss resistance representing the core loss

N_1, N_2 = the primary and referred secondary self or stray capacitance respectively

R_b = load resistance referred to the primary turns ratio.

A high permeability core with polished pole faces results in a large flux contribution, improving the coupling. Open circuit inductance will be high, leakage inductance is kept low compared to this main inductance.

Ring cores are very suitable since they have no air gap and make full use of the high permeability of the ferrite.

The frequency response of a practical transformer is shown in Fig.9.

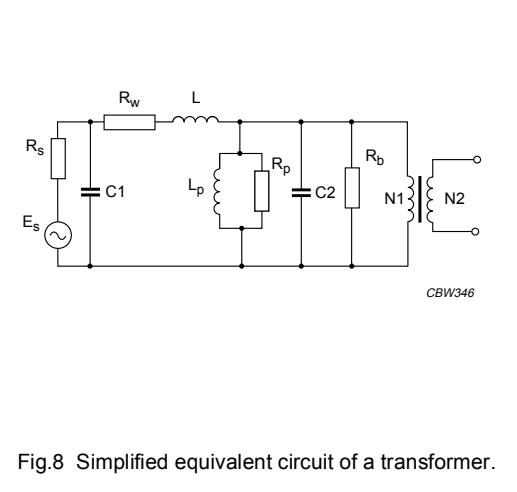

Fig.8 Simplified equivalent circuit of a transformer.

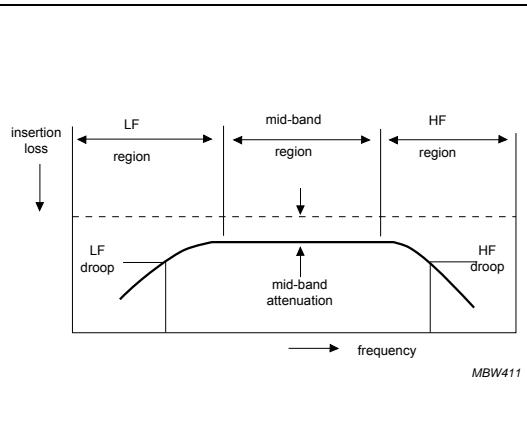

Fig.9 Transmission characteristic of a wideband transformer.

Soft Ferrites

Applications

The corresponding distortion of a rectangular pulse by the same circuit is shown in Fig.10.

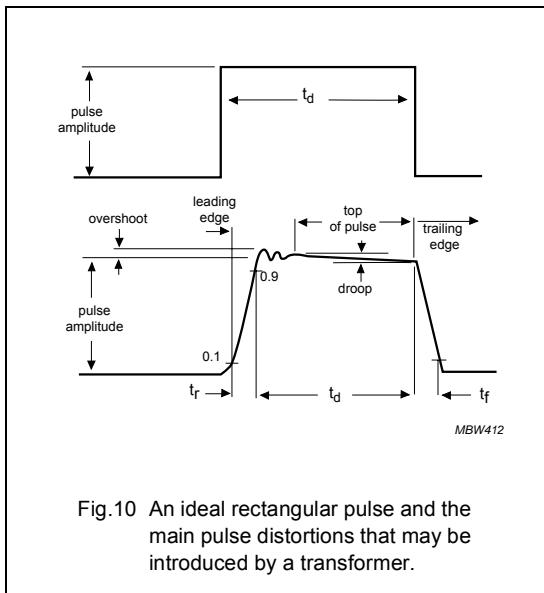

Fig.10 An ideal rectangular pulse and the main pulse distortions that may be introduced by a transformer.

The shunt inductance (L_p) is responsible for the low frequency droop in the analog transformer since its reactance progressively shunts the circuit as the frequency decreases. In the case of the pulse transformer, the shunt inductance causes the top of the pulse to droop, because, during the pulse, the magnetizing current in L_p rises approximately linearly with time causing an increasing voltage drop across the source resistance.

The winding resistance is the main cause of the mid-band attenuation in low frequency analog transformers. In a pulse transformer, it attenuates the output pulse but usually has little effect on the pulse distortion.

The high frequency droop of an analog transformer may be due to either the increasing series reactance of the leakage inductance or the decreasing shunt reactance of the self-capacitances, or a combination of both as the frequency increases. In a pulse transformer, the leakage inductance, self-capacitances and the source or load resistance combine to slow down, or otherwise distort the leading and trailing edge responses.

Suitable core types for this application in the materials 3E1, 3E4, 3E27, 3E28, 3E5, 3E55, 3E6, 3E7 and 3E8 are:

- P cores
- RM cores
- EP cores
- Ring cores
- Small ER cores
- Small E cores.

If the signal is superimposed on a DC current, core saturation may become a problem. In that case the special DC-bias material 3E28 or a lower permeability material such as 3H3, 3C81 or 3C90 is recommended.

Gapping also decreases the effect of bias currents.

Soft Ferrites

Applications

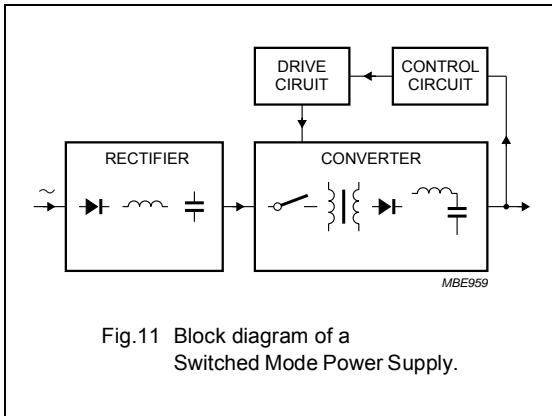

Ferrites for Power conversion

Power conversion is one of the major application areas for ferrites and is generally realized by using a switched mode power supply (SMPS). The basic arrangement of a SMPS is shown in Fig.11. In a SMPS, power is efficiently converted into the voltage and current levels, required by the end-application. The wide area in which SMPSs are applied can be divided into four parts: DC-DC, DC-AC, AC-DC and AC-AC. Although every converter type can be found for power conversion, most SMPS applications are based upon the DC-DC (e.g. battery operated equipment) and DC-AC types (e.g. inverters or lamp drivers). Note that many of these converters still have an AC-DC front-end, most of the times nothing more than a rectifier, a smoothing capacitor and a filter for EMC reasons. This front-end does not belong to the SMPS itself and ferrites used in the EMC filter will be treated in the part about interference suppression.

Numerous converter types exist, but most SMPS applications make use of one of the following types :

- Buck or down converter (DC-DC)
- Boost or up converter (DC-DC)
- Flyback converter (DC-DC)
- Forward converter (DC-DC)
- Half and full bridge converter (DC-AC)

Their basic operation principle will first be discussed and after this the focus is put on how to choose the appropriate core material.

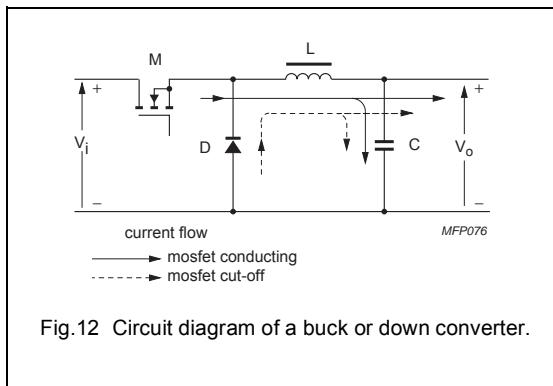

BUCK OR DOWN CONVERTER

With a buck or down converter, as shown in Fig.12, it is possible to adapt the input voltage to a lower level. It also means that the average output current is larger than the input current. The basic operation is as follows. During the on-time of the mosfet, a linearly rising current is flowing from the input to the output and energy is stored in the inductor (note that always the largest part of the energy is stored in the air gap and a minor part in the ferrite itself). By the end of the on-time, defined by the ratio of the output voltage and the input voltage, the mosfet is switched off. According to Lenz' law, the inductor voltage reverses and the stored energy results in a decreasing output current via the diode.

Dependent on the operating condition defined by the load, the current through the inductor will be mainly DC (continuous mode) with a triangular ripple on top of it. This means that the ferrite is operating around a DC bias point of B and H. Around this point a minor BH loop can be found.

In all those applications where a lower voltage is needed than the available supply voltage (e.g. automotive), buck converters can be found. Another application can be a so-called voltage regulated module (VRM) behind the standard computer power supply or Silver Box to deliver a stable processor voltage even under high load variations.

Soft Ferrites

Applications

BOOST OR UP CONVERTER

Re-arranging the circuit components of the buck converter results in the boost or up converter of Fig.13. It adapts the DC input voltage to a higher output level. When the mosfet is on, the inductor voltage is equal to the input voltage and the linearly rising current stores energy in the inductor. Switching off the mosfet stops the storage of energy and the inductor voltage reverses. The output voltage becomes the sum of the input and inductor voltage and a decreasing inductor current will be forced to flow to the output via the diode.

Typical boost converter applications can be found in battery operated equipment, e.g. a laptop where higher internal voltages are needed than supplied by the battery. In order to meet the stringent requirements on EMC, boost converters can also be used as power factor correction (PFC) circuits in between the mains and a SMPS. A PFC circuit ensures that a sinusoidal voltage and current are drawn from the mains, which is not possible with a SMPS only.

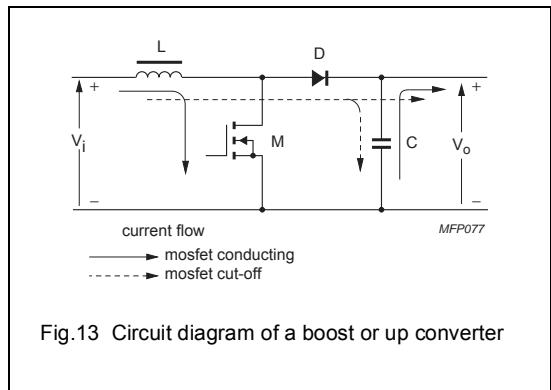

Fig.13 Circuit diagram of a boost or up converter

FLYBACK CONVERTER

One of the major drawbacks of both buck and boost converter is the absence of galvanic isolation between in- and output, which can be required by some applications. Introducing a magnetically coupled coil, like in the flyback converter of Fig.14, solves this point. But the big advantage of the flyback converter is that the output voltage can be higher or lower than the input voltage, depending on the turns ratio N . More secondary windings result in more output voltages. During the on-time of the mosfet, a linearly rising current is flowing through the primary winding and energy will be stored in the coupled coil. By the end of the on-time the primary voltage reverses and the stored energy introduces, via the magnetic coupling, a linearly decreasing current in the secondary

winding. The dots close to the primary and secondary windings indicate the winding direction, necessary for good operation.

The galvanic isolation between in- and output and the possibility of multiple outputs make the flyback converter one of the most popular SMPS types. Flyback converters can be found in many applications from small low power stand-by supplies of less than 1 W to big power supplies delivering over a few kWs.

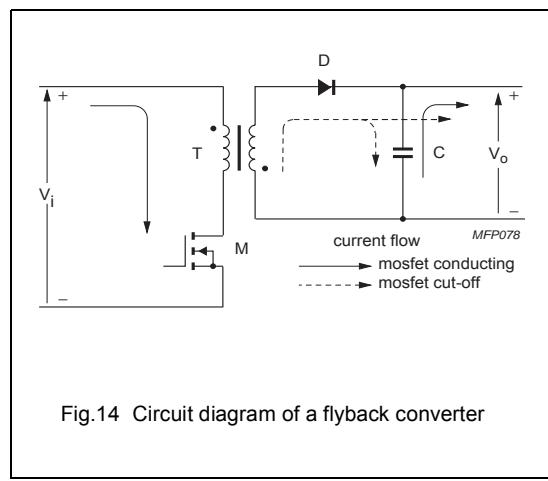

Fig.14 Circuit diagram of a flyback converter

FORWARD CONVERTER

The forward converter of Fig.15 is basically a buck converter with galvanic isolation realized by the transformer. With the turns ratio, the output voltage can be made higher or lower than the input voltage. When the mosfet is on, current is flowing through both the primary and secondary winding of the transformer and it will be magnetized. The secondary current stores energy in the coil. Switching off the mosfet releases the energy and a decreasing current is flowing to the output. De-magnetizing of the transformer is achieved by a third winding having an equal number of turns but opposite winding direction. With its higher component count, the forward converter is less attractive than the flyback converter.

A push-pull converter is an arrangement of two forward converters operating in antiphase (push-pull action). A push-pull converter circuit doubles the frequency of the ripple current in the output filter and, therefore, reduces the output ripple voltage. A further advantage of the push-pull operation is that the transformer core is excited alternately in both directions in contrast to both the forward and

Soft Ferrites

Applications

flyback converters. Therefore, for the same operating conditions and power throughput, a push-pull converter design can use a smaller transformer core.

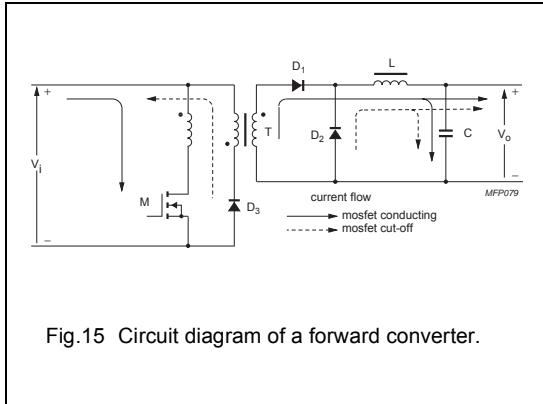

Fig.15 Circuit diagram of a forward converter.

HALF AND FULL BRIDGE CONVERTER

With the half bridge converter of Fig.16, one side of the primary winding is at a voltage potential equal to half the supply voltage. Switching the mosfets puts the other side alternately to the supply voltage and ground and therefore the primary voltage is half the supply voltage. However, with the full bridge converter, see Fig.17, and using the same transformer, the primary voltage is equal to the supply voltage. This makes the full bridge converter more efficient, but the control of two pairs of mosfets is more complicated. Transformer de-magnetizing is in both converters realized by the body diodes of the mosfets. For example, magnetizing of the transformer core is done with M_1 , while the de-magnetizing is done by the body diode of M_2 . An advantage of this principle is that M_2 can be switched on during the de-magnetizing process and no switch-on losses (the so-called zero voltage switching ZVS principle) occur and less EMI is generated.

The advantage of the bridge converters compared to the previous ones (except the push-pull converter) is that the transformer is excited in two directions and therefore the full BH loop from $-B_{sat}$ to $+B_{sat}$ can be used. For equal throughput power, the transformer of a bridge converter can be smaller than e.g. the transformer of a forward converter operating on the same frequency.

With a secondary circuit identical to that of a forward converter, the DC-AC converter is transformed into a DC-DC converter. Still, the operating frequency of the energy storage inductor is twice the control frequency and the ripple current has been halved. Therefore, the core volume of the inductor can also be smaller.

Half and full bridge converters are normally the basis for resonant converters. In these converters, the primary inductance is a part of a resonant tank made with one or more capacitors and/or inductors. Although the resonant tank has a squarewave input voltage, sinusoidal voltages and currents appear in the tank. This means that no harmonics are introduced and in combination with the ZVS of the mosfets, it makes resonant converters very attractive for high frequency designs. Note that resonant converters directly deliver their energy to the load and no energy storage inductor is necessary.

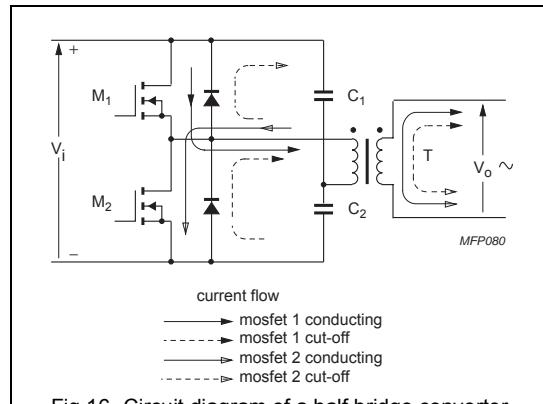

Fig.16 Circuit diagram of a half bridge converter.

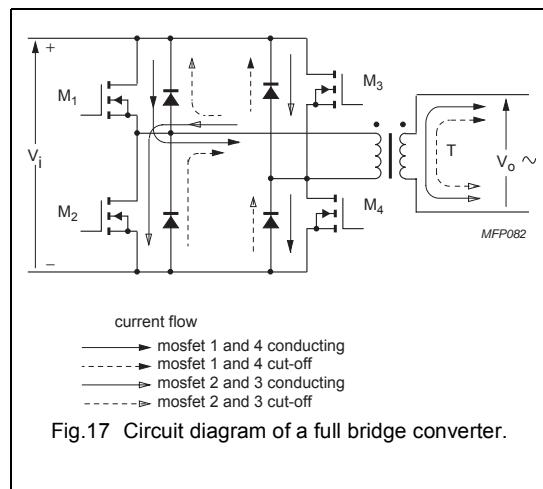

Fig.17 Circuit diagram of a full bridge converter.

Soft Ferrites	Applications
----------------------	---------------------

FERRITE SELECTION

Dependent on the converter type, the ferrites used in these converters operate under saturation or loss limited conditions, which require special power ferrites with high saturation and low loss levels even at elevated operation temperatures.

The operating frequency is one of the parameters defining which core material can be used in an application. For those SMPSs which are connected directly to a high input voltage (e.g. the rectified mains can be up to 400 V in some parts of the world), semiconductors with a high breakdown voltage are needed. A high breakdown voltage limits the switching frequency otherwise severe switching losses inside the semiconductor occur (on the other hand, a low voltage device can be used at much higher operating frequencies). For flyback converters things are even worse. When the mosfet is switched off, its drain-source voltage is the sum of input and rectified secondary voltage. Therefore the operating frequency of a high voltage input SMPS is limited by the capabilities of the used semiconductors and switching frequencies up to 300 kHz can be found nowadays even when the semiconductors are connected to a heatsink. This means that most power ferrites of the 3Cxx series will mainly be used under saturation limited conditions, see also the performance factor graph in Fig.19. On top, for many applications the operating frequency is only a few tens of kHz due to EMC regulations. The reason is that these requirements can relatively easily be met in the frequency area below 150 kHz.

Converters which are not directly connected to a high input voltage and/or soft-switching power supplies, like half and full bridge (resonant) converters can overcome this problem and operating frequencies into the MHz range can be found. Power ferrites for this range are gathered in the 3Fxx series and 4F1.

The energy storage inductor of all converters (except flyback and resonant) normally operates at a bias level, therefore ferrites with a high saturation value at the application temperature, like 3C92, result in the smallest core volumes.

In case of post regulators, the operating frequency can be chosen much higher as the input voltage is much lower and the generated EMI will be sufficiently attenuated by the SMPS in front of the post regulator. Now ferrites from the 3Fxx series and 4F1 are the best choice.

All the inductors, including the coupled inductor of the flyback converter, need an air gap necessary for the energy storage, while the transformers can be made without gap.

CORE SELECTION**OPERATING FREQUENCY**

The preferred operating frequency of a Switched Mode Power Supply is greater than 20 kHz to avoid audible noise from the transformer. With modern power ferrites the practical upper limit has shifted to well over 1 MHz.

Ambient temperature

Ambient temperature, together with the maximum core temperature, determines the maximum temperature rise, which in turn fixes the permissible total power dissipation in the transformer. Normally, a maximum ambient temperature of 60 °C has been assumed. This allows a 40 °C temperature rise from the ambient to the centre of the transformer for a maximum core temperature of 100 °C. There is a tendency however towards higher temperatures to increase power throughput densities. Our new material 3C93 meets these increased temperature requirements with a loss minimum around 140 °C

Flux density

To avoid saturation in the cores the flux density in the minimum cross-section must not exceed the saturation flux density of the material at 100 °C. The allowable total flux is the product of this flux density and the minimum core area and must not be exceeded even under transient conditions, that is, when a load is suddenly applied at the power supply output, and maximum duty factor occurs together with maximum supply voltage. Under steady-state conditions, where maximum duty factor occurs with minimum supply voltage, the flux is reduced from its absolute maximum permissible value by the ratio of the minimum to maximum supply voltage (at all higher supply voltages the voltage control loop reduces the duty factor and keeps the steady-state flux constant).

The minimum to maximum supply voltage ratio is normally taken as 1 : 1.72 for most applications.

Soft Ferrites	Applications																		
SELECTING THE CORRECT CORE TYPE	3C90 Low frequency (< 200 kHz) material for industrial use.																		
The choice of a core type for a specific design depends on the design considerations and also on the personal preference of the designer. Table 1 gives an overview of core types as a function of power throughput and this may be useful to the designer for an initial selection. Each of the core types has been developed for a specific application, therefore they all have advantages and drawbacks depending on, for example, converter type and winding technique.	3C91 Medium frequency (< 300 kHz) material with loss minimum around 60 °C. 3C92 Low frequency (< 200 kHz) material with a very high saturation level. Specially recommended for inductors and output chokes. 3C93 Medium frequency (< 300 kHz) material with loss minimum around 140 °C. 3C94 Medium frequency material (< 300 kHz). Low losses, especially at high flux densities. 3C96 Medium frequency (< 400 kHz) material. Very low losses, especially at high flux densities. 3F3 High frequency material (up to 700 kHz). 3F35 High frequency material (up to 1 MHz). Very low losses, around 500 kHz. 3F4 High frequency material (up to 2 MHz). Specially recommended for resonant supplies. 3F45 High frequency material (up to 2 MHz). Specially recommended for resonant supplies. 3F5 High frequency material (up to 4 MHz). Specially recommended for resonant supplies. 4F1 High frequency material (up to 10 MHz). Specially recommended for resonant supplies.

Choice of ferrite for power transformers and inductors

A complete range of power ferrites is available for any application.

3C30

Low frequency (< 200 kHz) material with improved saturation level. Suitable for flyback converters e.g. Line Output Transformers.

3C34

Medium frequency (< 300 kHz) material with improved saturation level. Suitable for flyback converters e.g. Line Output Transformers.

3C81

Low frequency (< 100 kHz) material with loss minimum around 60 °C.

Soft Ferrites

Applications

Performance factor of power ferrites

The performance factor ($f \times B_{\max}$) is a measure of the power throughput that a ferrite core can handle at a certain loss level. From the graph it is clear that for low frequencies there is not much difference between the materials, because the cores are saturation limited. At higher frequencies, the differences increase. There is an optimum operating frequency for each material. It is evident that in order to increase power throughput or power density a high operating frequency and a better ferrite should be chosen.

OUTPUT CHOKES

Output chokes for Switched Mode Power Supplies have to operate with a DC load causing a bias magnetic field H_{DC} .

In a closed ferrite circuit, this can easily lead to saturation. Power ferrites such as 3C90 or 3F3 start saturating at field strengths of about 50 A/m. Permeability drops sharply, as can be seen in the graphs of the material data section. The choke loses its effectiveness. The new material 3C92 is optimized for use in power inductors. It features a very high saturation level as well as a high T_c , making it the best

material for power inductors, especially at elevated temperatures.

There are two remedies against the saturation effect:

- The use of gapped ferrite cores
- The use of a material with low permeability and high saturation, like iron powder 2P.

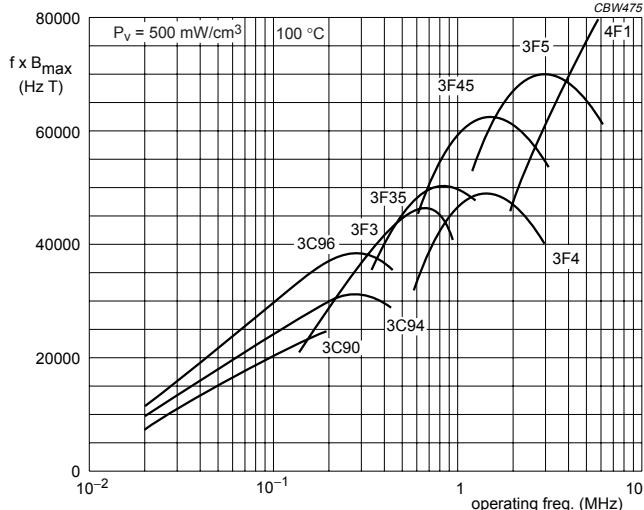

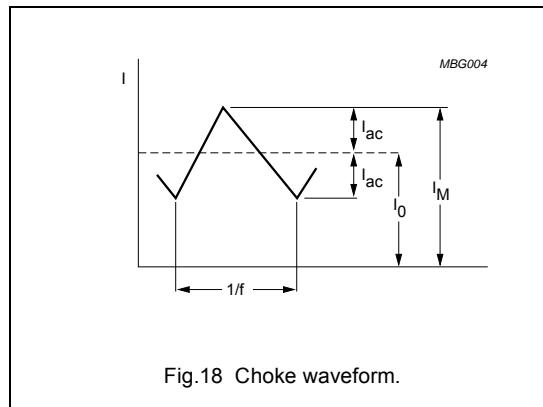

Fig.19 Performance factor ($f \times B_{\max}$) at
 $P_V = 500 \text{ mW/cm}^3$ as a function of frequency for power ferrite materials.

Soft Ferrites

Applications

GAPPED CORE SETS

The effect of an air gap in the circuit is that a much higher field strength is needed to saturate a core.

For each operating condition an optimum air gap length can be found. In a design, the maximum output current (I) and the value of inductance (L) necessary to smooth the ripple to the required level are known.

The product I^2L is a measure of the energy which is stored in the core during one half cycle.

Using this I^2L value and the graphs given on the following pages for most core types, the proper core and air gap can be selected quickly at a glance.

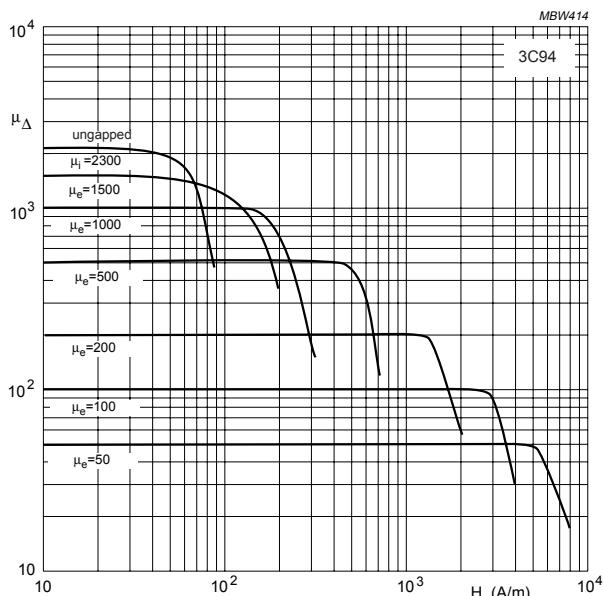

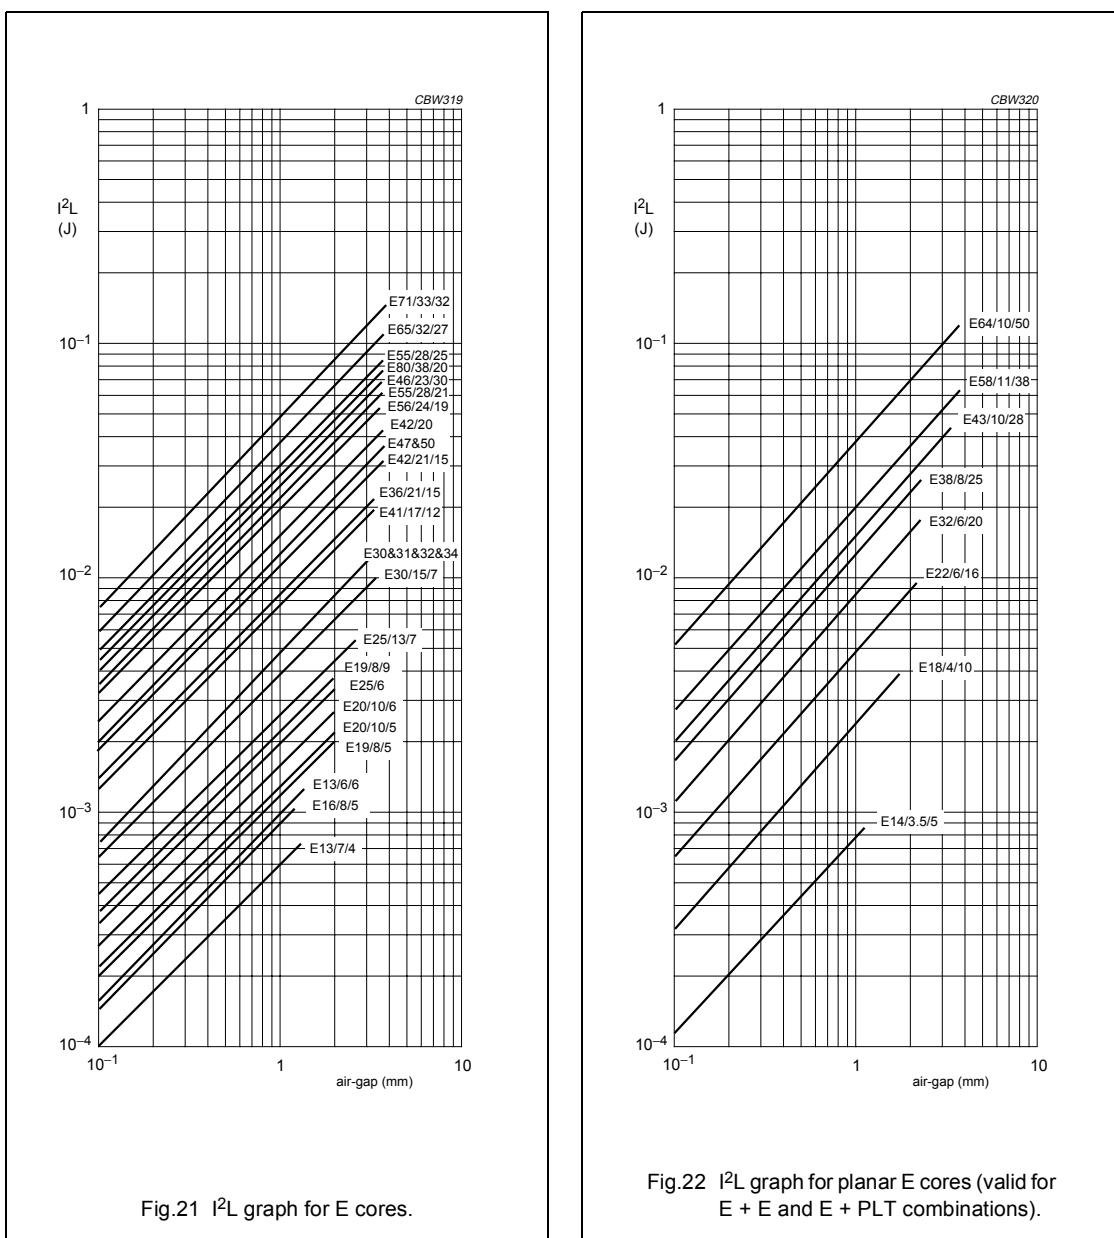

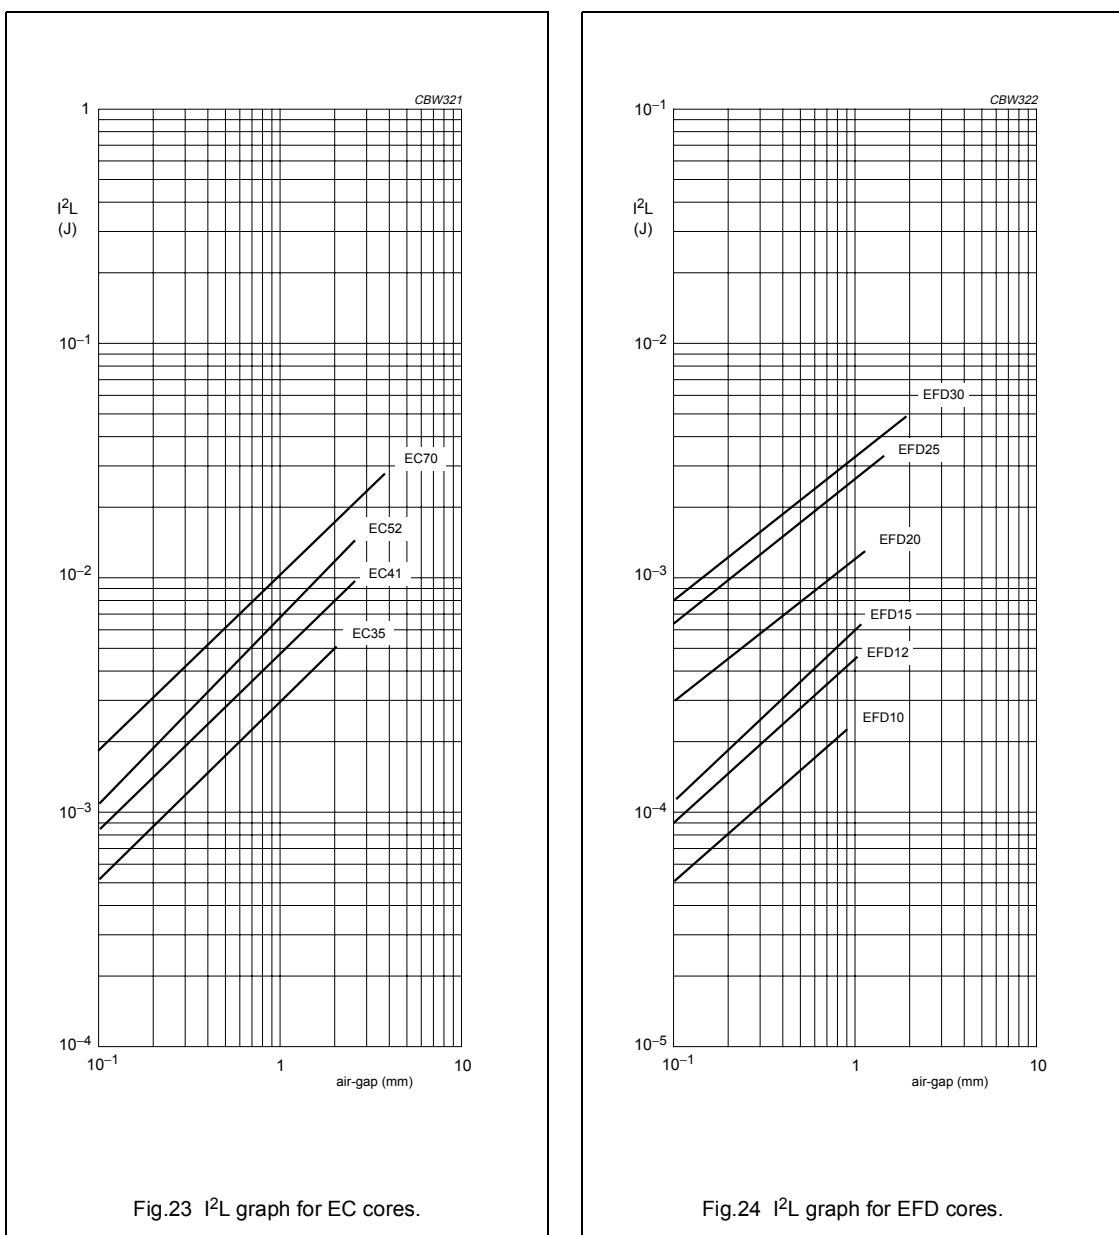

Fig.20 Effect of increased gap length.

Applications

IRON POWDER RING CORES

Ring cores made from compressed iron powder have a rather low permeability (max. 90) combined with a very high saturation level (up to 1500 mT). The permeability is so low because the isolating coating on the iron particles acts as a so called distributed air gap. Therefore, our 2P ring core range can operate under bias fields of up to 2000 A/m.

INPUT FILTERS (COMMON MODE CHOKES)

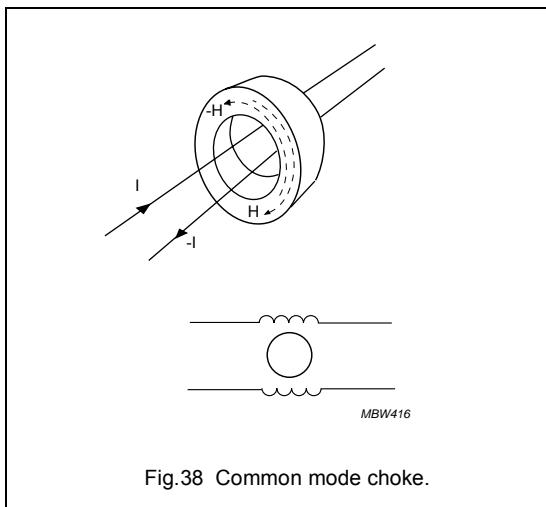

Fig.38 Common mode choke.

To avoid the conduction of switching noise from a SMPS into the mains, an input filter is generally necessary. The magnetic circuit in these filters is usually a pair of U cores or a ring core.

Since the noise signal is mainly common mode, current compensation can be used to avoid saturation.

Two separate windings on the core cause opposing magnetic fields when the load current passes through them (current compensation). The common mode noise signal however, is blocked by the full inductance caused by the high permeability ferrite.

If, for some reason, current compensation is not complete or impossible, high permeability materials will saturate. In that case one of the power materials may be a better compromise. Another important factor in the design process is the frequency range of the interference signal. High permeability ferrites have a limited bandwidth as can be seen from Fig.39.

These materials only perform well as an inductor below the frequency where ferromagnetic resonance occurs. Above this cut-off frequency, a coil will have a highly resistive character and the Q-factor of the LC filter circuit will be limited and thus, also the impedance. A better result could have been obtained with a grade having a lower permeability. Fig.40 provides a quick method of choosing the right ferrite for the job.

Soft Ferrites

Applications

3R1 TOROIDS IN MAGNETIC REGULATORS

Saturable inductors can be used to regulate several independent outputs of an SMPS by blocking varying amounts of energy from the secondary of the transformer. The rectangular BH loop of our 3R1 ferrite toroids makes them ideal for magnetic regulators with reset control. The circuits required are both simple and economic and can be easily integrated.

Operating principles

When the main switch is ON (t_{on}) the output current (I_{out}) flows through the winding of the saturable inductor to the output inductor and from there to the load.

During OFF time this current falls to zero and so does the magnetic field H. Because the saturable inductor has a rectangular B-H loop, the flux remains at the high level B_r even when the driving field H has fallen to zero.

When no reset current is applied, the flux in the toroid remains at the level of B_r until the next ON time starts. There is only a short delay (t_d) because the flux rises from B_r to B_s . After that, the current rises sharply to its maximum value, limited only by the load impedance. The output voltage has its maximum value, given by:

$$V_{out} = V_t \times \frac{t_{on} - t_d}{T}$$

When V_{out} is higher than V_{ref} a reset current flows during OFF time, regulated by the transistor. This current can only flow through the winding of the saturable inductor.

Because this current causes a magnetic field in reverse direction it will move the ferrite away from saturation. Resetting to $-H_c$, for instance, causes some extra delay (t_b) because of the larger flux swing. Full reset causes a flux swing of almost $2 \times B_s$, resulting in a maximum delay ($t_d + t_b$) and the blocking of a major part of the energy flowing from the transformer to the load. The output voltage is regulated to the required level and is given by:

$$V_{out} = V_t \times \frac{t_{on} - t_d - t_b}{T}$$

In this way a reset current in the order of 100 mA can regulate load currents in the order of 10 A or more, depending on the layout of the saturable inductor. For this reason the described circuit is called a magnetic regulator or magnetic amplifier.

The performance of the material 3R1 is comparable to that of amorphous metal making it an excellent choice for application in magnetic regulators. However, since the value of H_c is higher for the ferrite than for most amorphous metal compositions, a simple replacement will often fail to deliver the expected results. A dedicated design or a slight redesign of the regulating circuit is then required, for which we will be glad to give you advice.

Behaviour of the ferrite material in a saturable inductor is shown in Fig.41.

Soft Ferrites

Applications

Ferrites for Interference Suppression and Electromagnetic Compatibility (EMC)

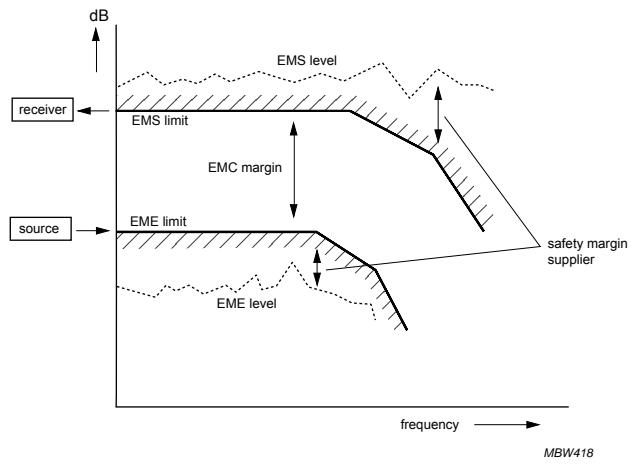

Fig.45 Principles of Electromagnetic Compatibility (EMC).

With the ever increasing intensive use of electronic equipment Electromagnetic Compatibility (EMC) has become an important item. Laws specify limits of the level of interference caused by equipment (EME) and also the sensitivity of equipment to incoming interference (EMS).

Limiting curves are defined by organizations such as EU and FCC. Since the density of equipment increases, laws will become more stringent in the near future.

During the design phase, problems with interference can be avoided to some extent. Often additional suppression components such as capacitors and coils will be necessary to meet the required levels. Inductive components are very effective in blocking interfering signals, especially at high frequencies. The principles of suppression are shown in Fig.46.

Capacitors are used as a shunt impedance for the unwanted signal.

Unfortunately for high frequencies, most capacitors do not have the low impedance one might expect because of parasitic inductance or resistance.

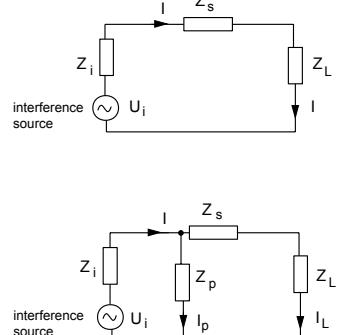

Fig.46 Basic suppression circuits.

Soft Ferrites

Suppressors are used in series with the load impedance. They provide a low impedance for the wanted signal, but a high impedance for the interfering, unwanted, signal.

Ferroxcube have a full range of ring cores, beads, multilayer suppressors and inductors, beads on wire, SMD beads, wideband chokes and cable shields to suit every application. Rods and tubes are also often used for this application after they have been coiled by the user.

SAMPLE BOXES

As the design process in these areas is often based on trial and error, we have assembled several

designers' sample boxes. Each box is filled with a selection from our standard ranges, which aims at a specific application area. The boxes also contain a booklet with full information about the products and their applications. These sample boxes are:

- Sample box 9: SMD beads and chokes
- Sample box 10: Cable shielding
- Sample box 11: EMI suppression products
- Sample box 12: Multilayer suppressors.
- Sample box 13: Multilayer inductors.

INTERFERENCE SUPPRESSION BEADS

A range of beads is available in two material grades, especially developed for suppression purposes.

They can easily be shifted on existing wires in the equipment:

- 3S1 for frequencies up to 30 MHz
- 3S4 for frequencies from 30 to 1000 MHz
- 4S2 for frequencies from 30 to 1000 MHz.

Applications

The materials and beads are fully guaranteed for their main feature, impedance as a function of frequency.

The grade 3S1 has a high permeability and is therefore rather sensitive for DC load. In applications where a high DC current is flowing 3S5 is a better choice, especially at elevated temperatures.

Soft Ferrites

Applications

BEADS ON WIRE

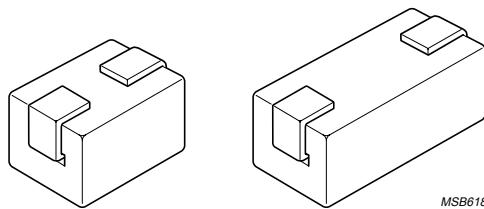

This product range consists of suppression beads, already mounted on pre-soldered 0.6 mm wire and taped on standard reels. These can be handled by automatic placement machines.

SMD FERRITE BEADS

In response to market demands for smaller, lighter and more integrated electronic devices a series of SMD beads was added to our range. They are available in different sizes and 2 suppression ferrite grades.

Basically these beads consist of a ferrite tube with a rectangular cross-section and a flat tinned copper wire which is bent around the edges and forms the terminals of the component. This design offers many superior mechanical and electrical features.

Some examples of their impedance as a function of frequency and the influence of bias current are given in the graphs.

Soft Ferrites

Applications

SMD FERRITE BEADS FOR COMMON-MODE INTERFERENCE SUPPRESSION

Ferrox cube has a range of soft ferrite SMD beads for common-mode interference suppression.

With standard suppression methods in a signal path, the wanted signal is often suppressed along with the interference, and in many modern applications (EDP for instance) this leads to unacceptable loss of signal.

In Ferrox cube's interference suppression beads, a pair of conductors within a single soft ferrite block are connected along their lengths by an air gap.

Common-mode signals (interference signals passing in the same direction along the input and output channels of a device, an IC for instance) serve to reinforce the magnetic flux around both conductors and are therefore attenuated.

In contrast, the wanted signal passing along the input and output channels serves to cancel the flux around the conductors and therefore passes unattenuated.

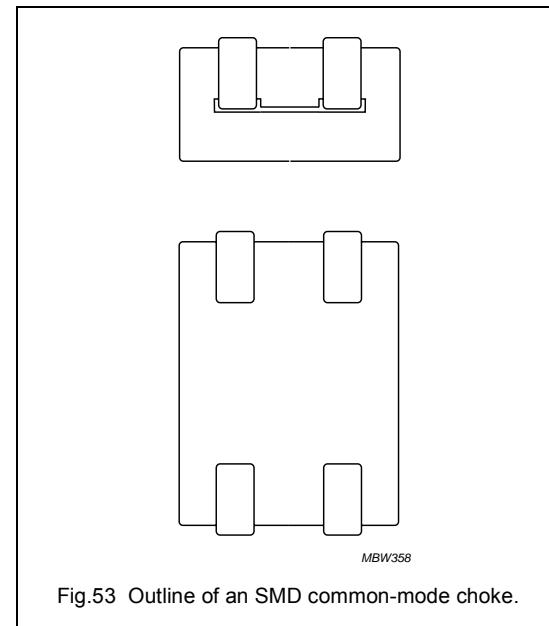

Fig.53 Outline of an SMD common-mode choke.

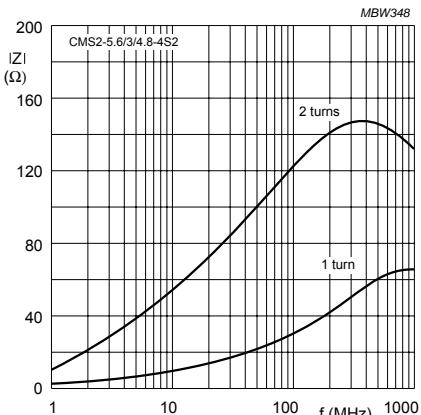

Fig.54 Impedance as a function of frequency of an SMD common mode bead with two conductors.

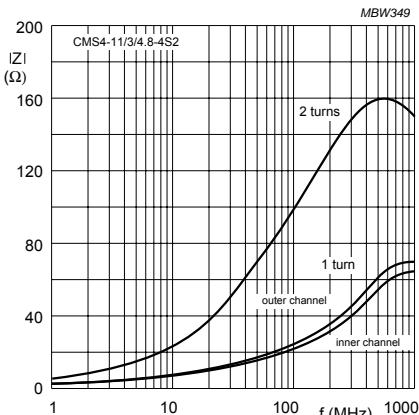

Fig.55 Impedance as a function of frequency of an SMD common mode bead with four conductors.

Soft Ferrites

Applications

WIDEBAND CHOKES

Wideband chokes are wired multi-hole beads. Since they have up to $2\frac{1}{2}$ turns of wire their impedance values are rather high over a broad frequency range, hence their name.

The magnetic circuit is closed so there is little stray field. The DC resistance is very low since only a short length of 0.6 mm copper wire is used.

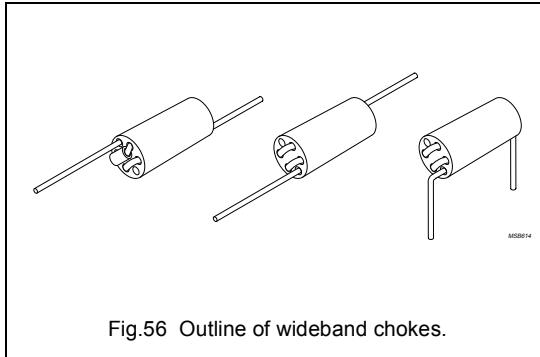

Fig.56 Outline of wideband chokes.

These products already have a long service record and are still popular for various applications.

The basic range has been extended with several types, e.g. with isolation and taped on reel.

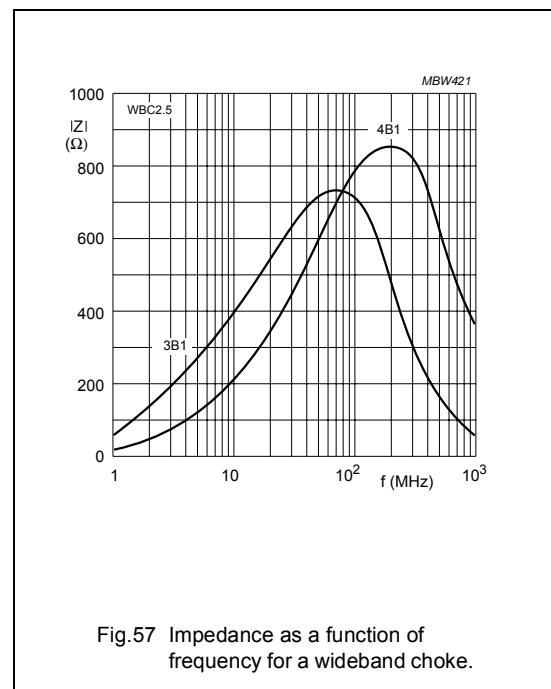

Fig.57 Impedance as a function of frequency for a wideband choke.

Soft Ferrites

Applications

SMD WIDEBAND CHOKES

SMD wideband chokes are an alternative to a SMD bead when more impedance or damping is required.

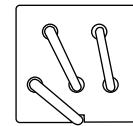

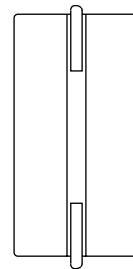

The design of this product is based on our well known range of wideband chokes.

In these products the conductor wire is wound through holes in a multi-hole ferrite core, thus separating them physically and reducing coil capacitance.

The result is a high impedance over a wide frequency range, a welcome feature for many interference problems.

The present SMD design preserves the excellent properties and reliability of the original wideband chokes by keeping the number of electrical interfaces to an absolute minimum.

A plated version is available to increase the soldering surface. The metallization does not extend to the edge of the core to allow for side-to-side mounting.

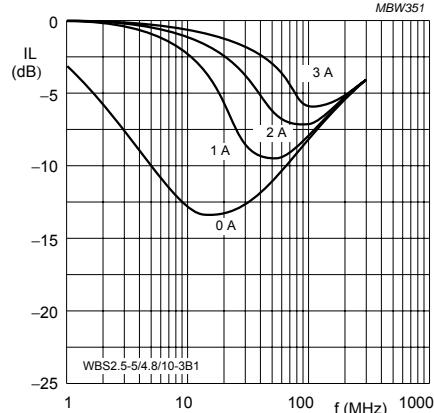

Fig.61 Insertion loss of a 3B1 SMD wideband choke as a function of frequency (50 Ω circuit).

Soft Ferrites

Applications

CABLE SHIELDS

Also in our range are so-called cable shields. These products are an effective remedy against common-mode interference on coaxial or flat cables. They come in several shapes: round tubes, rectangular sleeves and split sleeves to mount on existing cable connections.

Our suppression material 3S4 is very suitable for this application. It combines a high permeability (1700) for high impedance in the lower frequency range with an excellent high frequency behaviour for true wideband suppression.

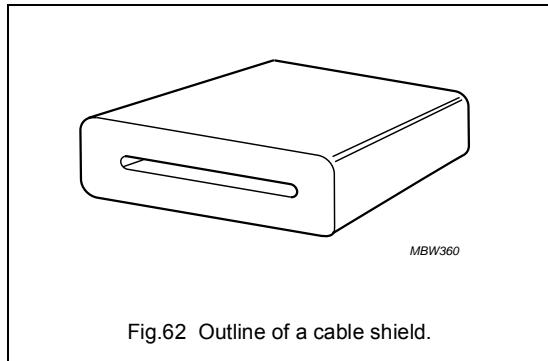

Fig.62 Outline of a cable shield.

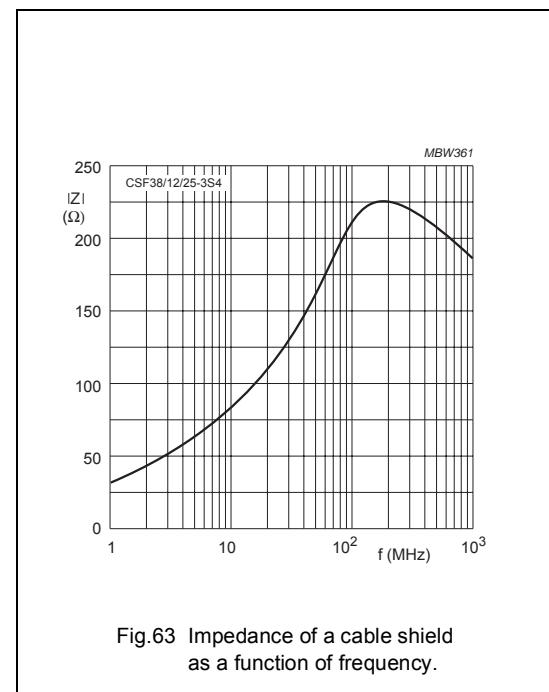

Fig.63 Impedance of a cable shield as a function of frequency.

Soft Ferrites

Applications

RODS AND TUBES

Rods and tubes are generally used to increase the inductance of a coil. The magnetic circuit is very open and therefore the mechanical dimensions have more influence on the inductance than the ferrite's permeability (see Fig.64) unless the rod is very slender.

In order to establish the effect of a rod on the inductance of a coil, the following procedure should be carried out:

- Calculate the length to diameter ratio of the rod (l/d)
- Find this value on the horizontal axis and draw a vertical line.

The intersection of this line with the curve of the material permeability gives the effective rod permeability.

The inductance of the coil, provided the winding covers the whole length of the rod is given by:

$$L = \mu_0 \mu_{\text{rod}} \frac{N^2 A}{l} (\text{H})$$

where:

N = number of turns

A = cross sectional area of rod

l = length of coil.

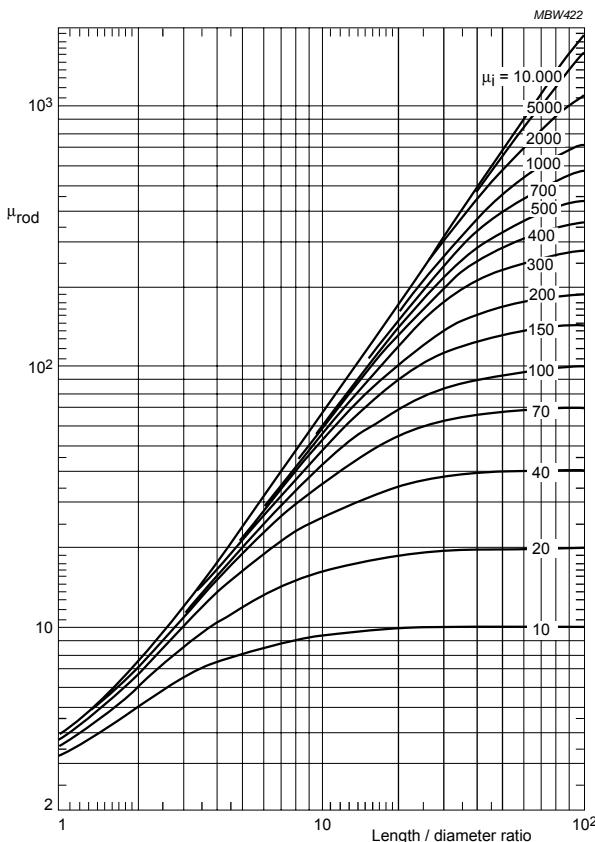

Fig.64 Rod permeability (μ_{rod}) as a function of length to diameter ratio with material permeability as a parameter.

Ferroxcube

Soft Ferrites

Soft Ferrites

Ferrite materials survey

Properties specified in this section are related to room temperature (25 °C) unless otherwise stated. They have been measured on sintered, non ground ring cores of dimensions Ø25 × Ø15 × 10 mm which are not subjected to external stresses. Products generally comply with the material specification. However, deviations may occur due to shape, size and grinding operations etc. Specified product properties are given in the data sheets or product drawings.

Soft Ferrites

RESISTIVITY

Ferrite is a semiconductor with a DC resistivity in the crystallites of the order of $10^{-3} \Omega\text{m}$ for a MnZn type ferrite, and about $30 \Omega\text{m}$ for a NiZn ferrite.

Since there is an isolating layer between the crystals, the bulk resistivity is much higher: 0.1 to $10 \Omega\text{m}$ for MnZn ferrites and 10^4 to $10^6 \Omega\text{m}$ for NiZn and MgZn ferrites.

This resistivity depends on temperature and measuring frequency, which is clearly demonstrated in Tables 1 and 2 which show resistivity as a function of temperature for different materials.

Table 1 Resistivity as a function of temperature of a MnZn-ferrite (3C94)

TEMPERATURE (°C)	RESISTIVITY (Ωm)
-20	≈ 10
0	≈ 7
20	≈ 4
50	≈ 2
100	≈ 1

Table 2 Resistivity as a function of temperature of a NiZn-ferrite (4C65)

TEMPERATURE (°C)	RESISTIVITY (Ωm)
0	$\approx 5 \cdot 10^7$
20	$\approx 10^7$
60	$\approx 10^6$
100	$\approx 10^5$

At higher frequencies the crystal boundaries are more or less short-circuited by their capacitance and the measured resistivity decreases, as shown in Tables 3 and 4.

Table 3 Resistivity as function of frequency for MnZn ferrites

FREQUENCY (MHz)	RESISTIVITY (Ωm)
0.1	≈ 2
1	≈ 0.5
10	≈ 0.1
100	≈ 0.01

Ferrite materials survey

Table 4 Resistivity as function of frequency for NiZn ferrites

FREQUENCY (MHz)	RESISTIVITY (Ωm)
0.1	$\approx 10^5$
1	$\approx 5 \cdot 10^4$
10	$\approx 10^4$
100	$\approx 10^3$

PERMITTIVITY

The basic permittivity of all ferrites is of the order of 10. This is valid for MnZn and NiZn materials. The isolating material on the grain boundaries also has a permittivity of approximately 10. However, if the bulk permittivity of a ferrite is measured, very different values of apparent permittivity result. This is caused by the conductivity inside the crystallites. The complicated network of more or less leaky capacitors also shows a strong frequency dependence.

Tables 5 and 6 show the relationship between permittivity and frequency for both MnZn and NiZn ferrites.

Table 5 Permittivity as a function of frequency for MnZn ferrites

FREQUENCY (MHz)	PERMITTIVITY (ϵ_r)
0.1	$\approx 2 \cdot 10^5$
1	$\approx 10^5$
10	$\approx 5 \cdot 10^4$
100	$\approx 10^4$

Table 6 Permittivity as a function of frequency for NiZn ferrites

FREQUENCY (MHz)	PERMITTIVITY (ϵ_r)
0.001	≈ 100
0.01	≈ 50
1	≈ 25
10	≈ 15
100	≈ 12

Material specification

3R1

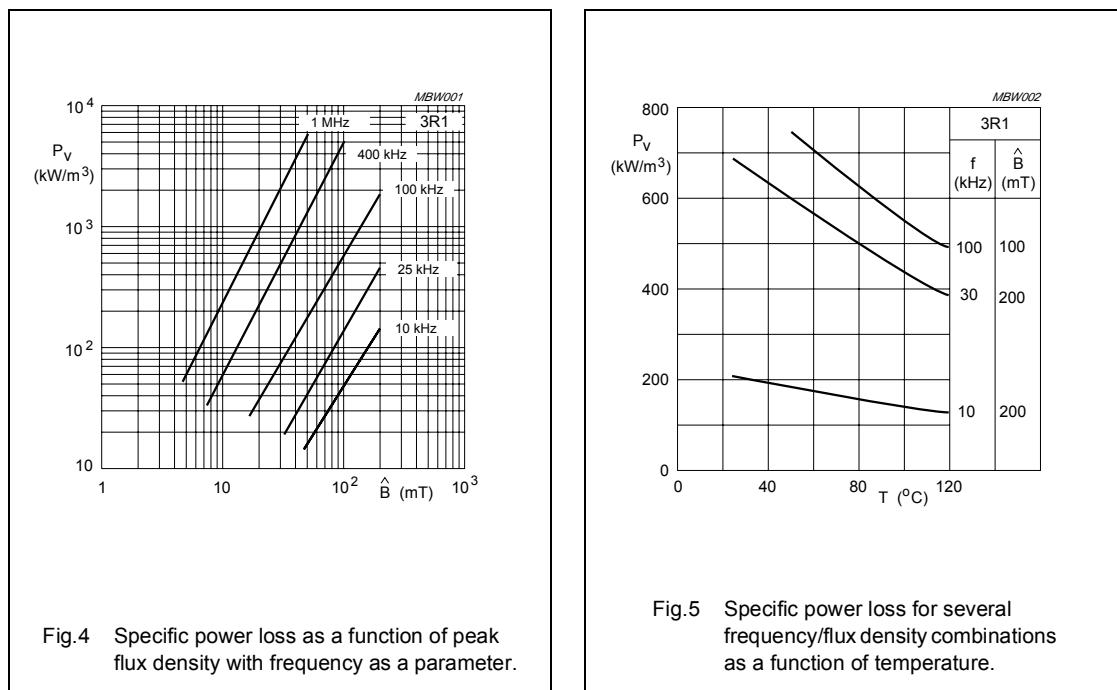

Fig.4 Specific power loss as a function of peak flux density with frequency as a parameter.

Fig.5 Specific power loss for several frequency/flux density combinations as a function of temperature.

Remark:

When 3R1 ring cores are driven exactly at their natural mechanical resonant frequencies a magneto-elastic resonance will occur. With large flux excursions and no mechanical damping, amplitudes can become so high that the maximum tensile stress of the ferrite is exceeded. Cracks or even breakage of the ring core could be the result. It is advised not to drive the toroidal cores at their radial resonant frequencies or even subharmonics (e.g. half this resonant frequency).

Resonant frequencies can be calculated for any ring core with the following simple formula:

$$f_r = \frac{5700}{\pi \left(\frac{D_o + D_i}{2} \right)} \text{ kHz}$$

where:

f = radial resonant frequency (kHz)

D_o = outside diameter (mm)

D_i = inside diameter (mm).

Material specification

3S1

3S1 SPECIFICATIONS

A low frequency EMI-suppression material specified on impedance and optimized for frequencies up to 30 MHz.

SYMBOL	CONDITIONS	VALUE	UNIT
μ_i	25 °C; ≤10 kHz; 0.25 mT	≈ 4000

Soft Ferrites

INTRODUCTION

Ferrites are used not only in the known consumer and professional electronics applications, but also in science and industry. The specifications and tolerances required for scientific and industrial applications are generally very demanding and critical. Experts in ceramic technologies know that making ferrite is one thing, machining it to close tolerances is another.

Hence there are only a few ferrite manufacturers in the world who can deliver ferrites with the required magnetic properties and within critical tolerances.

FERROXCUBE is one of those few manufacturers but with a difference. We bring along with us the experience gained by supplying customized products to some of the most prestigious scientific institutions and industries.

This means we can support you in finding the best solution for any inductive component you may need. Especially if your requirements cannot be met with ferrite cores from our standard ranges.

Being a major worldwide supplier of a wide variety of Soft Ferrites gives us the experience and know-how to support such projects.

2. Blocks
3. Special shapes
4. Tiles

1. Ferrite in scientific particle accelerators (RINGS)

The application

Ferrites are used extensively in modern scientific experiments. One of the most exciting and advanced applications is in particle accelerators. Scientists are trying to discover the mysteries of the universe by smashing atomic particles with titanic forces. This requires particle beams to be accelerated to very high speeds and guided into a collision chamber with the help of specially designed magnetic rings.

Specialty Ferrites

Our materials

Ferroxcube's research and development can build on 50 years' experience in ferrite technology. We developed the required materials which fulfil the demanding specifications. Due to our long involvement with ferrite technology, we are one of only two major suppliers in the world who support such demanding projects. Because of the extremely demanding nature of the specifications, these magnetic rings are designed and developed in close interaction with the scientists. This has enabled us to develop unique material grades, which are processed in our highly controlled production environment to deliver the required product performance.

Our product range

Our range of large ring cores was developed especially for use in scientific particle accelerators. Applications include mainly RF cavities. Dynamic behaviour under pulse conditions is important for those applications, so special ferrite grades are optimized for low losses at high flux densities. These large rings have also been used successfully in delay lines for very high power such as in pulsed lasers or radar equipment. Sizes given on the drawings are just an example of our capability. Generally, all rings are made with dimensions agreed on request. Please contact us to discuss your needs.

General properties of the grades are described in the section on Material Grades. Specific properties, related to their use in particle accelerators, are provided in the following table.

Relevant properties of ferrites in accelerator applications

Properties specified in this section are related to room temperature (25 °C) unless otherwise stated. They have been measured on sintered, non-ground ring cores of dimension Ø36 × Ø28 × 6 mm which are not subjected to external stresses.

Products generally do not fully comply with the material specification. Deviations may occur due to shape, size and grinding operations. Detailed specifications are given in the data sheets or product drawings.

Specialty Ferrites

2. FERRITE BUILDING BLOCKS

Rectangular ferrite blocks can be used for 2 purposes :

- Machining specialty shapes
Ferrites are hard and brittle materials and difficult to machine (see also next section). Normally FERROXCUBE will do this job.
- Building large structures
Blocks can be combined to create magnetic structures e.g. equivalent to U or E core sets. Maximum block size is 270 x 250 x 75 mm if the material has to be fired in another atmosphere than pure air. Blocks can be used to create larger "cores", in a simple and flexible way.

Blocks are ground on all sides to a tolerance of ± 0.1 mm, with special attention to parallel and perpendicular surfaces.

Soft Ferrites

3. MACHINED FERRITES AND SPECIALTY SHAPES

We stock most of our material grades in blocks and are able to machine numerous prototype cores. Very close tolerances can be realized if required.

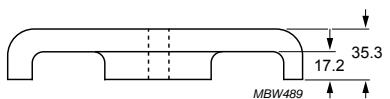

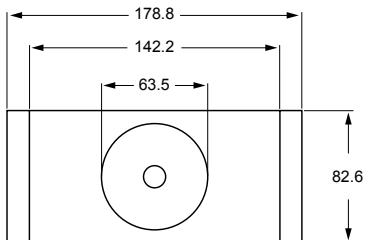

Ferrites, being very hard and brittle are difficult to work. The machining and grinding of ferrites and similar materials to micron precision, places stringent requirements on machines and men. To attain optimum standards requires close cooperation between us, the manufacturers of the machines and the machine tools we use.

There are several reasons to choose machined ferrite cores.

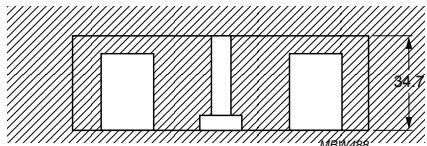

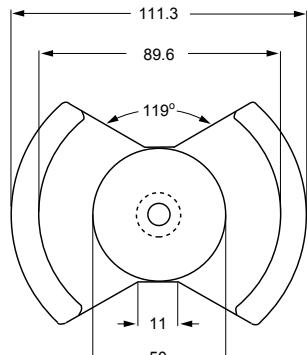

1. Only a limited number of cores is needed and it is not worthwhile to make a tool at all.
2. Tolerances required are so tight that machining is the only viable solution.
3. Shape is so complicated that it can't be pressed.
4. Samples are required prior to making a tool.

The drawings provide a good impression of the variety of cores we have produced. For some of the cores we also have pressing tools available.

4. FERRITE IN ANECHOIC CHAMBERS FOR EMI MEASUREMENT (TILES)

The application

Regulations are in place for every kind of electromagnetic interference from equipment. Especially free field radiation limits would require outdoor testing and would need a lot of space. This can be overcome with the help of anechoic chambers. They have walls with a very low reflection and thus approach outdoor testing. Ferrite tiles are a compact alternative to large carbon pyramid absorbers, to reduce the size of EMI test chambers.

Our product range

The absorber material 4S60 has been designed for broadband operation (up to 1000 MHz). Its parameters were matched to achieve low reflection of incident waves. The high-frequency losses of the ferrite do the rest of the job as the wave travels up and down the tile. See the material specification section for all characteristics of 4S60.

Common tile size is 100 x 100 mm, available with and without hole for screw mounting and gluing respectively. All sides are ground to tight tolerances to achieve flatness and squareness for optimum performance of the tiled chamber walls.

(1) The technology utilized in conjunction with the coupled inductor ("the CL") described in this data sheet includes intellectual property (the "IP") owned by iWatt, Inc. and is covered by one or more of the following U.S. patents : 6,545,450 ; 6,686,727 ; 6,696,823. In connection with the end customer's purchase of the CL from "Ferroxcube USA", the end customer is hereby granted a non-exclusive, worldwide, royalty-free license (without rights to sublicense) to use and incorporate the IP in the end customer's product that also incorporates the CL. In no way does this license extend to customer end products which do not incorporate the CL to implement the IP.

T	0.35	± 0.1	mm

Note

1. P₀ pitch tolerance over any 10 pitches is ± 0.2 mm.

Reel specifications**Storage requirements**

These storage requirements should be observed in order to ensure the soldering of the exposed electrode:

- Maximum ambient temperature shall not exceed 40 °C. Storage temperature higher than 40 °C could result in the deformation of packaging materials.
- Maximum relative humidity recommended for storage is 70% RH. High humidity with high temperature can accelerate the oxidation of the tin-lead plating on the termination and reduce the solderability of the components.
- Products shall not be stored in environments with the presence of harmful gases containing sulfur or chlorine.

Tag plate	material: phenolformaldehyde (PF), glass reinforced	3	TGP-P42/29-C
	flame retardant: in accordance with "UL 94V-0"; UL file number E41429		
	maximum operating temperature: 180 °C, "IEC 60085", class H		
	pins: copper-tin alloy (CuSn), tin (Sn) plated		
	resistance to soldering heat in accordance with "IEC 60068-2-20", Part 2, Test Tb, method 1B: 350 °C, 3.5 s		
	solderability in accordance with "IEC 60068-2-20", Part 2, Test Ta, method 1: 235 °C, 2 s		
Container	copper-zinc alloy (CuZn), tin (Sn) plated	4	CON-P42/29
	earth pins: presoldered		
Spring	CrNi-steel	5	SPR-P42/29
	spring force: ≈350 N when mounted

COIL FORMERS**General data**

PARAMETER	SPECIFICATION
Coil former material	phenolformaldehyde (PF), glass reinforced, flame retardant in accordance with "UL 94V-0"; UL file number E167521(M)
Pin material	copper-tin alloy (CuSn), tin (Sn) plated
Maximum operating temperature	180 °C, "IEC 60085", class H
Resistance to soldering heat	"IEC 60068-2-20", Part 2, Test Tb, method 1B, 350 °C, 3.5 s
Solderability	"IEC 60068-2-20", Part 2, Test Ta, method 1

**Ferroxtag RFID
transponders**

For more information on Product Status Definitions, see page 3.

Soft Ferrites**Ferroxtag RFID transponders****FERROXTAG****Smart on metal, Smart on liquid, Smart at speed**

Ferroxtag is a new family of RFID (Radio Frequency IDentification) tags suitable for operation attached to metallic items, such as totes, barrels, gas cylinders and industrial equipment. Operation frequency is 13.56 MHz. Ferroxtag's key feature is the direction of the field activating the device : it is not perpendicular to the identified item but parallel to it ; this means that the performance is almost independent of the material of the item identified. There's no need to worry about electromagnetic reflection on metals.

The Ferroxtag core is an outstanding high magnetic permeability ferrite material that enhances the performance of the winding, thus reducing the dimensions of the coil. There are 3 versions of the tag : screw box, circuit mount and L-shape.

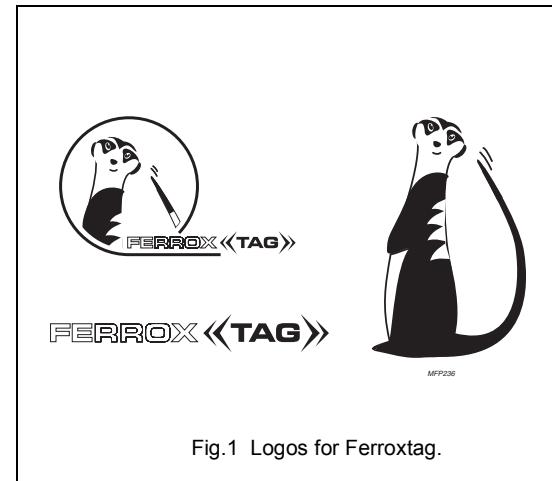

Fig.1 Logos for Ferroxtag.

Applications

- Asset tracking
- Food traceability
- Process control
- Personal identification
- Counterfeiting prevention
- Luggage tracking
- Animal identification

PRODUCT DESCRIPTION**General**

SCREW BOX	CIRCUIT MOUNT	L-SHAPE
a High Frequency (13.56 MHz) RFID tag optimized for identification of metallic items. Supports ISO15693 and ISO18000-3 air interface.		
It can be screwed to the item and/or stuck on it with the bottom side adhesive tape. The reading range is 30 cm on metal. Overall dimensions are 25 x 12.5 x 5 mm, including the holes for screws.	It can be soldered on a PCB like any SMD component. The reading range is 30 cm on metal. Overall dimensions are 15 x 8 x 2.5 mm.	An ID number bar code is printed on the encapsulation. This allows fast automatic reading through RFID technology and reading with a standard bar code reader. The reading range is 35 cm. The encapsulation protects the device while it eases the mounting on the corner of the item by means of the adhesive sticker supplied in the back.

Ferroxtag RFID transponders

PRODUCT DESCRIPTION (Continued)

Mechanical properties

SCREW BOX	CIRCUIT MOUNT	L-SHAPE
Operating temperature -25...130 °C Dimensions 25 x 12.5 x 5 mm Weight 2.5 grams Case material Polyamide 66 UL94-V0 compliant sealed with epoxy resin Degree of protection IP68 Colors Black, blue, brown, beige Connection to items Screws, glue, double sided adhesive tape	Operating temperature -25...130 °C Dimensions 15 x 8 x 2.5 mm Weight 2.5 grams Connection to PCB Soldering as SMD component	Operating temperature -25...60 °C Dimensions 42 x 20 x 12 mm Weight 3.5 grams Case material ABS Degree of protection IP68 Colors Black, others upon request Connection to items Glued or stuck
Ferroxtag mechanical properties make this product ideal for metal container and metallic items identification. The encapsulation protects the device against impacts and harsh environments, making it suitable for industrial applications.	Ferroxtag mechanical properties make this product ideal for electronics identification. The tag can be soldered anywhere on a PCB.	Ferroxtag mechanical properties make this product ideal for identification in the vicinity of metallic items. The encapsulation protects and eases the installation in a wide range of boxes and assets.

Functional properties

SCREW BOX	CIRCUIT MOUNT	L-SHAPE
	Operating frequency 13.56 MHz (ISM, licence free) Air interface ISO 15693, ISO 18000-3 Readable and writable with most common HF readers Unique identifier 8 bytes EEPROM memory 1024 bits, 32 blocks of 4 bytes Anticollision support Yes Data transfer Up to 53 kbits/sec	
Reading range On metal 30 cm (typical for 4 watts reader)		Reading range 35 cm (typical for 4 watts reader) Bar code printing Thermally printed on 12 x 24 mm sticker Bar code ID Last 4 bytes of the tag ID (8 hex characters)
The outstanding reading range in such a small package combined with the ability to work around metals makes Ferroxtags an ideal alternative for both low and high frequency tags.		Thanks to the double identification (RFID and bar code) it is possible to identify the item in the field with a hand held bar code reader.

Soft Ferrites

RFID transponder cores

INTRODUCTION

Transponders are electronic devices capable of sending short RF messages upon request. These messages are commonly used to identify something where the transponder is attached, but can be used to send data as well. The term transponder comes from transmitter / responder.

There are many different types of transponders, depending on the final use of the transponder, and on the operating frequency. Low Frequency Magnetic Communication (below 500 kHz) commonly uses ferrite cores to increase the performance (and distance range) of the transponder.

Ferroxcube provides a wide range of ferrite cores fitting many of the existing market requirements, as well as years of experience in designing custom shapes for specific needs. New materials have been developed improving temperature stability and reaching higher permeability values. In addition, advanced features like metallized contacts or tighter tolerances on mechanical and electrical parameters are feasible.

Newly developed materials include 4B2 and 4B4 improving the temperature stability and robustness of the complete system thanks to their high density structure. Also 3B7 has been optimized for the transponder shapes. Ferroxcube materials cover a wide range of needs, from temperature stability with αF as low as 1 (from -40 to +85°C) to high Q factor with $tg\delta/\mu$ lower than 100×10^{-6} at 500 kHz. They are available in Nickel Zinc (4B1, 4B2, 4B4) high resistivity and Manganese Zinc (3C90, 3B7).

Special features

PVD metallized terminals on request.

- Best adhesion ferrite-metallization-PCB.
- High accuracy layer thickness and size of the footprint.
- Low height metallization provides optimum Q factor.

Tightest length tolerance.

- Absolute tolerance down to ± 0.1 mm.
- Minimizes the spread in electrical properties.

Advanced features

- Diameter tolerance down to ± 0.015 mm on ground rods.
- Length tolerance down to ± 0.2 mm on rods.
- Inductance sorting out in groups of $\pm 1\%$.
- Minimum rod diameter down to 0.3 mm.
- Parylene-C coating on rods and other shapes.
- Metallized terminals in silver palladium for SMD products.
- Custom shapes available on request.

Applications

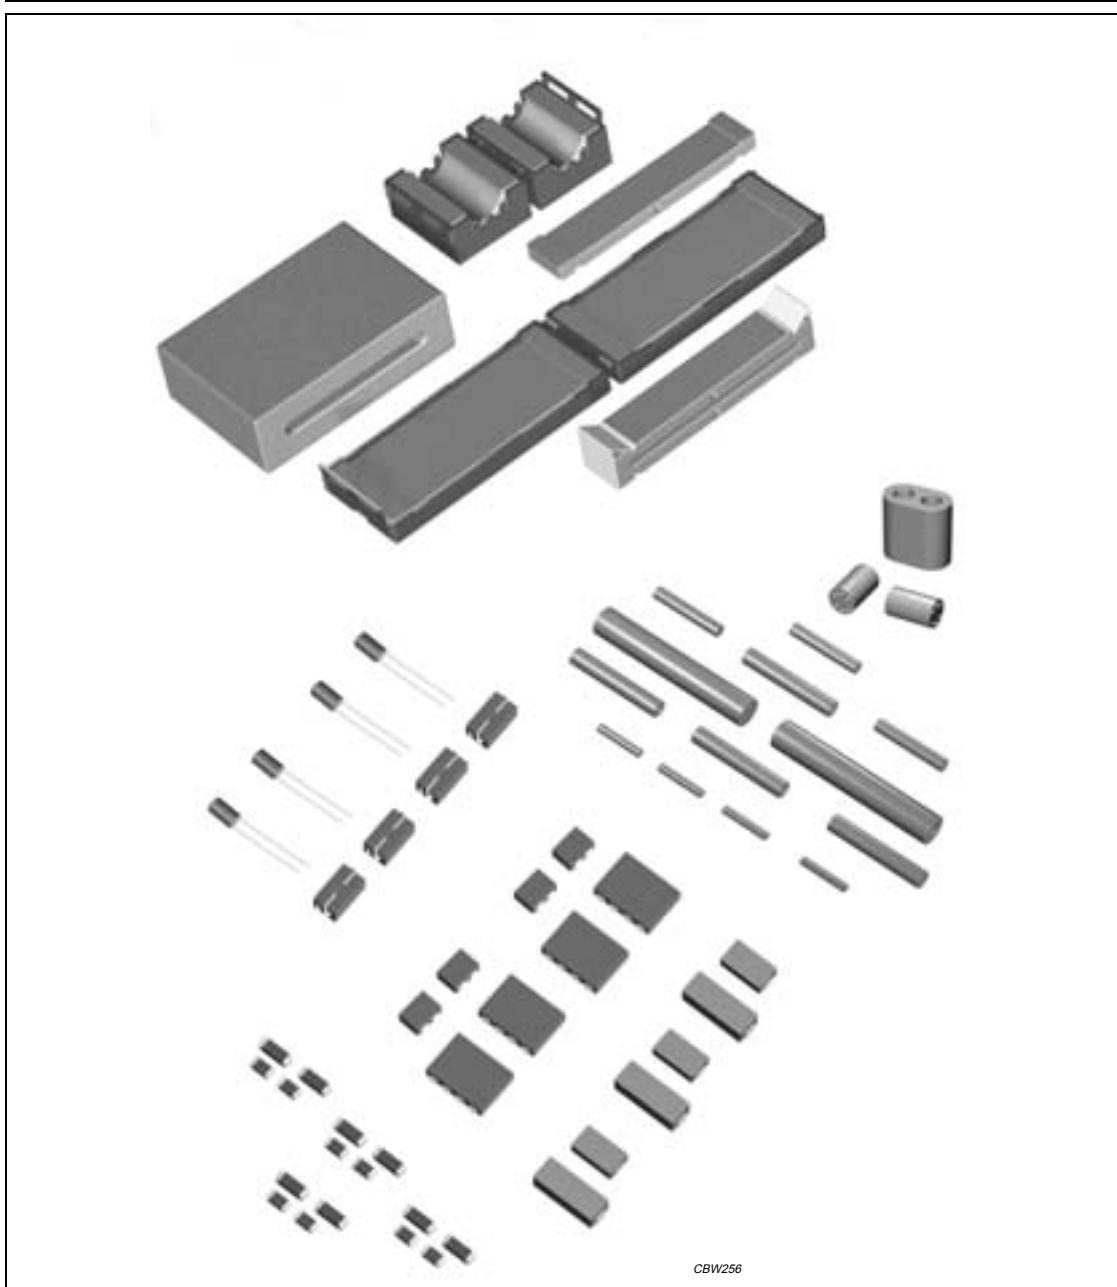

- Automotive
- Wireless sensors
- Asset tracking
- Food traceability
- Process control
- Personal identification
- Counterfeiting prevention
- Luggage tracking
- Animal identification

Soft Ferrites

Soft Ferrites

EMI-suppression products

CBW256

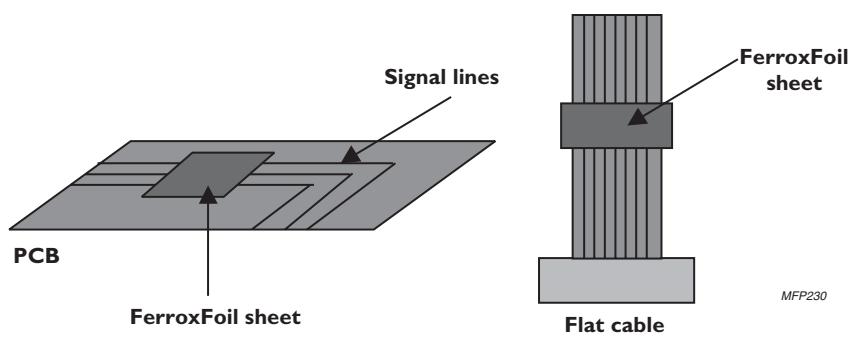

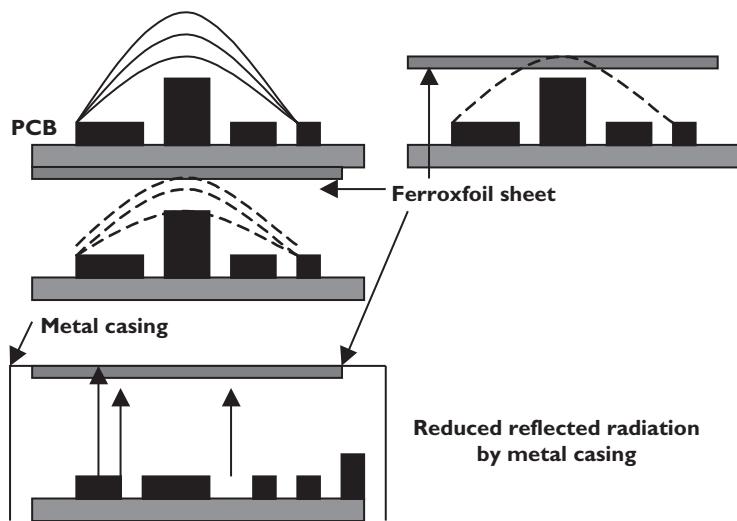

Soft Ferrites**EMI-suppression products****PRODUCT OVERVIEW AND TYPE NUMBER STRUCTURE****Product overview EMI-suppression products**

CORE TYPE	DESCRIPTION
BAR	bar
BC	bobbin core
BD	bead
BDS	bead SMD
BDW	bead on wire
CLI-CSU	clip for CSU type cable shield
CMS	common mode choke SMD
CSA	cable shield arcade
CSA-EN	cable shield arcade encapsulated
CSC	cable shield C-shape
CSC-EN	cable shield C-shape encapsulated
CSF	cable shield flat
CST	cable shield tubular
CSU	cable shield U-shape
CSU-EN	cable shield U-shape encapsulated
FAR	flat antenna rod
FXF	Ferroxfoil flexible sheet EMI absorber
FXT	Ferrotag RFID tag
MHB	multihole core binocular (incl miniature balun core)
MHC	multihole core circular
MHR	multihole core rectangular
MLH	multilayer inductor high frequency
MLI	multilayer inductor
MLN	multilayer suppressor narrowband
MLP	multilayer suppressor power
MLS	multilayer suppressor
ROD	rod
TUB	tube
WBC	wideband choke
WBS	wideband choke SMD
WBSM	wideband choke SMD metallized
T	toroid (ring core)
TAR	transponder antenna rod
TC	toroid coated with parylene C
TL	toroid coated with lacquer (converted to epoxy)
TN	toroid coated with nylon
TX	toroid coated with epoxy

EMI-suppression products

Ferroxfoil EMI absorber sheet

FerroxFoil - Flexible sheet EMI absorbers

Radiated EMI can be confined by enclosing the source in a metal box. This reflects the signal back without attenuation and will not lower the general noise level around the source. It's better to enclose the source with an absorbing material. That is the case with FerroxFoil products, consisting of a sheet of absorptive material, constituted by a lossy magnetic material distributed in an organic matrix, which absorbs the electromagnetic energy of the incident radiation and converts it into heat. Its flexible structure provides an excellent processability and allows its use in a huge variety of configurations and applications : the sheets can easily be cut to custom shapes and sizes and wrapped closely around the radiation source. This makes them very well suited for retrofit solutions if the source of interference has not been found yet. Moreover, with its high electrical resistivity it can be applied on conductive material. The materials are effective in the wide frequency band 100 MHz - 30 GHz and one HF material around the RFID frequency 13.56 MHz. Ferroxfilm comes in four different grades :

- 5W1 The basic grade
- 5R1 High resistivity for high insulation
- 5F1 Higher frequencies (500 MHz - 30 GHz)
- 5T1 Shielding metal parts in RFID at 13.56 MHz

For all grades, the sheets are available with different thickness, depending on the degree of attenuation required.

Applications / Examples of use

Applications can be found where ever radiated EMI is present : in the far field (prevention of EMI radiation and protection against incoming EMI) or in the near field (between components on a PCB, between PCB's, around transmission lines) and to shield metal objects for RFID in

the HF band (13.56 MHz). In the far field, plane waves coincide with the sheet surface and are either frontally reflected, absorbed in the sheet or transmitted. All materials have been engineered in such a way that reflection is low and absorption high. Reflection depends on the ratio of permeability and permittivity, while absorption depends on magnetic losses. In the near field, the geometry of the shielded object is important and it's difficult to give general rules other than absorption by magnetic losses.

Examples :

- Noise coupling reduction between components on the same PCB
- Top shields for fast digital IC's (clock, microprocessor, memory)
- Prevention of unwanted high frequency circuit resonances
- Noise coupling reduction between circuits on different (stacked) PCB's
- Noise coupling reduction between PCB circuits and an LCD display
- SAR regulation for mobile phones (human head protection)
- Noise absorption from PCB transmission lines and flat cable connections
- Noise absorption on steel casing inside to lower general radiation level
- Enhanced reading distance of RFID tags in the proximity of metals
- Directional shielding to prevent interference in wireless communication
- Directional shielding to prevent interference from radar equipment
- Directional shielding to prevent interference from medical equipment

Materials and properties

PARAMETER	5W1	5R1	5F1	5T1
Main Feature / Application	High Performance Wide Band	High Resistivity / High Insulation	HF Use / Semi-Microwave Band	RFID Applications
Recommended frequency range	100 MHz - 10 GHz	100 MHz - 10 GHz	500 MHz - 30 GHz	13.56 MHz
Operating temperature range (°C)			-25 to +125	
Resistivity (Ωm)	10	10^4	10	10
Density (g/cm^3), typical	3.0	3.0	4.0	3.0
Typical initial permeability (μ_i), 100 MHz	10	5	5	10
Min / Max sheet dimensions (mm)			50 x 50 / 300 x 200	
Min / Max sheet thickness (mm)			0.1 / 6.0	
Typical sheet dimensions / thickness (mm)			100 x 100 x 0.5	
			100 x 100 x 1.0	
Environment			RoHS Compliant : Lead Free / Halogen Free

EMI-suppression products

Multilayer inductors

MULTILAYER INDUCTORS

Our range of multilayer inductors offers magnetic shielding, in five standard sizes (0402, 0603, 0805, 080505 and 1206), which are specially designed for miniaturized electronic products. It offers minimum flux leakage thus eliminating cross talk. They have inductances between 1 nH and 18 mH.

Main applications areas for multilayer inductors are:

- computer and peripheral equipment: mother board, notebook, CD-Rom, DVD-Rom, CD-RW, scanner, hard disc, VGA card, sound card, LCD monitor, printer, PC server thumb drive, PCMCIA card, graphic card, etc.
- network: LAN card, hub, switcher, router set top box, etc.
- telecom: cell phone, ADSL, wired modem, cable modem, ISDN, GPS satellite receiver, etc.
- consumer: walkman, walkdisc, digital still camera (DSC), sound system, HDTV, projector, DVD player, VCD player, tuner for TV, cable modem, etc.

Main high frequency application for multilayer inductor MLH are:

- cell phone, dect phone, wireless LAN card, wireless micro-phone, TV tuner, RF receiver, cable modem, RF amplifier, security remote control, wireless mouse, wireless keyboard pager, set top box.

To help designers in the trial and error process of finding the most suitable component, we offer a sample box with a selection of products.

Ordering code: SAMPLEBOX13

Features

- Monolithic structure for closed magnetic path and high reliability.
- Standard EIA and EIAJ sizes: 0402, 0603, 0805, 080505, 1206.
- This multilayer chip inductor results in magnetic shielding: the absence of leakage flux makes it most suitable for high density mounting.
- Suitable for wave and reflow soldering.
- Plating material lead-free
- Wide range of inductance values.
- Superior physical properties.
- Available in standard EIA and EIAJ tape-and-reel.
- Operating temperature -40°C to +125°C.
- 100% sorting out on inductance. Product construction

EMI-suppression products**Multilayer inductors****TYPE NUMBER STRUCTURE**

Type numbers for these products consist of the following:

- Product type
- Size
- Inductance
- Tolerance

Product type

MLI: Multilayer Inductor.

MLH: Multilayer inductor High frequency.

Size

0402: $1.0 \times 0.5 \times 0.5$ mm

0603: $1.6 \times 0.8 \times 0.8$ mm

0805: $2.0 \times 1.25 \times 0.9$ mm

080505: $2.0 \times 1.25 \times 1.25$ mm

1206: $3.2 \times 1.6 \times 1.1$ mm

Inductance values

Expressed in nH or μ H

Different ways to indicate the values are used.

EXAMPLES

4N7: 4.7 nH

82N: 82 nH

R10: 0.1 μ H

1R8: 1.8 μ H

820: 82 μ H

151: 150 μ H

Tolerance

The last 2 digits represent the tolerance:

05%, 10% or 20%

In MLH '03' the tolerance has the absolute value of ± 0.3 nH.

Multilayer Inductor MLI 0805-R68-10

TYPE	SIZE	INDUCTANCE	TOLERANCE
MLI	0805	0.68 μ H	$\pm 10\%$

Multilayer Inductor High frequency MLH 0402-4N7-03

TYPE	SIZE	INDUCTANCE	TOLERANCE
MLH	0402	4.7 nH	± 0.3 nH

EMI-suppression products

Multilayer suppressors

MULTILAYER SUPPRESSORS

Multilayer suppressors are a powerful solution for EMI/RFI attenuation for electronic equipment. Supplied in seven standard sizes (0402, 0603, 0805, 1206, 1210, 1806 and 1812), they have impedances between 6 and 2 000 Ω at 100 MHz.

When installed in series with signal and/or power circuits, high frequency noise is suppressed. There is no need for ground termination, which makes these devices very suitable for circuits with difficult ground. Typical suppression frequencies range from 10 MHz to 1 000 MHz and rated currents are between 0.1 and 6 A.

Multilayer suppressors are specially designed to reduce noise in low impedance circuits while keeping the signal free from distortion. This is because at the interfering frequencies these components behave as a resistor. The high frequency noise is converted into heat rather than reflected to the source. This dissipation prevents ringing and parasitic oscillations.

These characteristics can be used for many different purposes:

- Absorption of generated noise.
- Filtering and wave-shape correction of digital signals from high speed clock oscillators.
- Prevention of high frequency interference entering circuit electronics.

Features

- Monolithic structure for closed magnetic path and high reliability
- Standard EIA and EIAJ sizes:
0402, 0603, 0805, 1206, 1210, 1806 and 1812
- High impedance per volume which leads to effective high density circuits
- Suitable for wave and reflow soldering
- Plating material lead-free
- Wide range of impedance values
- Superior physical properties
- Available in standard EIA and EIAJ tape-and-reel
- Operating temperature -40°C to +125°C
- 100% sorting out on impedance

Main applications areas for multilayer suppressors are:

- computer and peripheral equipment: mother board, notebook, CD-Rom, DVD-Rom, CD-RW, scanner, hard disc, VGA card, sound card, LCD monitor, printer, PC server thumb drive, PCMCIA card, graphic card, etc.
- network: LAN card, hub, switcher, router set top box, etc.
- telecom: cell phone, ADSL, wired modem, cable modem, ISDN, GPS satellite receiver, etc.
- consumer: walkman, walkdisc, digital still camera (DSC), sound system, HDTV, projector, DVD player, VCD player, tuner for TV, cable modem, etc.

To help designers in the trial and error process of finding the most suitable suppression component, we offer a sample box with a selection of products.

Ordering code: SAMPLEBOX12

EMI-suppression products**Multilayer suppressors****TYPE NUMBER STRUCTURE**

Type numbers for these products consist of the following:

- Product type
- Size
- Impedance.

Product type

MLS: Multilayer Suppressor.

MLP: Multilayer Power Beads.

MLN: Multilayer Narrow Band.

Size

0402: $1.0 \times 0.5 \times 0.5$ mm

0603: $1.6 \times 0.8 \times 0.8$ mm

0805: $2.0 \times 1.25 \times 0.9$ mm

1206: $3.2 \times 1.6 \times 1.1$ mm

1210: $3.2 \times 2.5 \times 1.3$ mm

1806: $4.5 \times 1.6 \times 1.6$ mm

1812: $4.5 \times 3.2 \times 1.5$ mm.

Impedance value

Expressed in ohms (Ω)

First two digits are significant figures

Last digit is the number of zeros to follow.

EXAMPLES

600: 60Ω

101: 100Ω

121: 120Ω

151: 150Ω

301: 300Ω

102: 1000Ω

Multilayer Suppressor MLS0603-4S7-600

TYPE	SIZE	INTERNAL CODE	IMPEDANCE
MLS	0603	4S7	60

Multilayer Power Bead MLP0603-121

TYPE	SIZE	IMPEDANCE
MLP	0603	120

Multilayer Narrow Band MLN0603-601

TYPE	SIZE	IMPEDANCE
MLN	0603	600

Standard products are delivered taped on reel and have a tolerance on impedance of 25%.

Note

1. at 50 MHz
2. at 30 MHz

- RDC: Resistance of component for DC current.
- Maximum rated current: measure of current capacity of the component. When the maximum rated current is applied, temperature rise shall not exceed 20°C.
- Standard tolerance on impedance is ±25%.
- Other tolerances can be provided upon request.
- Operating temperature: -40°C to +125°C.

2. Also available with insulated wires, sleeves.

Dimensions in mm.

Fig.5 WBC2.5/R.

General data WBC2.5/SP

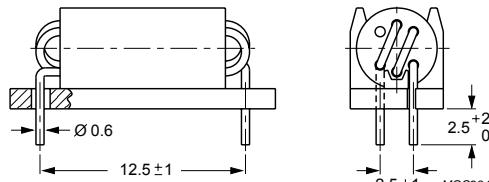

ITEM	SPECIFICATION
Wire material	copper (Cu), tin (Sn) plated
Support	polyamide (PA6.6) plate to allow mounting across circuit tracks; flame retardant in accordance with UL 94V-0
Solderability	"IEC 60068-2-20", Part 2, Test Ta, method 1

Grades, parameters and type numbers; see Fig.6

GRADE	No. OF TURNS	$ Z_{typ} $ at f (Ω)	$ Z_{typ} $ at f (MHz)	TYPE NUMBER
note 1	3S4	2.5	≥ 600	WBC2.5/SP-3S4 sup
	4B1	2.5	≥ 700	WBC2.5/SP-4B1 sup

Note

1. Colour code 3S4 = blue, 4B1 = green.

Dimensions in mm.

2. Due to the rectangular BH-loop of 3R1, inductance values strongly depend on the magnetic state of the ring core and measuring conditions. Therefore no A_L value is specified. For the application in magnetic amplifiers A_L is not a critical parameter.

WARNING

Do not use 3R1 cores close to their mechanical resonant frequency. For more information refer to "3R1" material specification in this data handbook.

1. Old permeability specification maintained.
2. Due to the rectangular BH-loop of 3R1, inductance values strongly depend on the magnetic state of the ring core and measuring conditions. Therefore no A_L value is specified. For the application in magnetic amplifiers A_L is not a critical parameter.

WARNING

Do not use 3R1 cores close to their mechanical resonant frequency. For more information refer to "3R1" material specification in this data handbook.

1. Old permeability specification maintained.
2. Due to the rectangular BH-loop of 3R1, inductance values strongly depend on the magnetic state of the ring core and measuring conditions. Therefore no A_L value is specified. For the application in magnetic amplifiers A_L is not a critical parameter.

WARNING

Do not use 3R1 cores close to their mechanical resonant frequency. For more information refer to "3R1" material specification in this data handbook.

m	mass of core	≈ 220	g

Coating

The cores are coated with epoxy, flame retardant in accordance with "UL 94V-0"; UL file number E 235873. The colour is white.

Maximum operating temperature is 200 °C.

Isolation voltage

DC isolation voltage: 2000 V.

Contacts are applied on the edge of the ring core, which is also the critical point for the winding operation.

V_e	effective volume	1880	mm^3
l_e	effective length	56.7	mm
A_e	effective area	33.1	mm^2
m	mass of core (for μ_i 125)	MPP	15.9 g
		Sendust	11.5 g
		High-Flux	15.0 g

Coating

The cores are coated with epoxy. The colour is black (Sendust), grey (MPP) or khaki (High-Flux). Maximum operating temperature is 200 °C.

Isolation voltage

AC isolation voltage : 1000 V.

Contacts are applied on the edge of the ring core, which is also the critical point for the winding operation.

RING CORES (TOROIDS)

Effective core parameters

SYMBOL	PARAMETER	VALUE	UNIT	
$\Sigma(I/A)$	core factor (C1)	0.540	mm^{-1}	
V_e	effective volume	21300	mm^3	
l_e	effective length	107	mm	
A_e	effective area	199	mm^2	
m	mass of core (for μ_i 125)	MPP	181	g
		Sendust	131	g
		High-Flux	171	g

Coating

The cores are coated with epoxy. The colour is black (Sendust), grey (MPP) or khaki (High-Flux). Maximum operating temperature is 200 °C.

Isolation voltage

AC isolation voltage : 1000 V.

Contacts are applied on the edge of the ring core, which is also the critical point for the winding operation.

l_e	effective length	17.3	mm
A_e	effective area	4.81	mm^2
m	mass of core	≈ 0.6	g

Coating

The cores are coated with polyamide 11 (PA11), flame retardant in accordance with "UL 94V-2"; UL file number E 45228 (M).

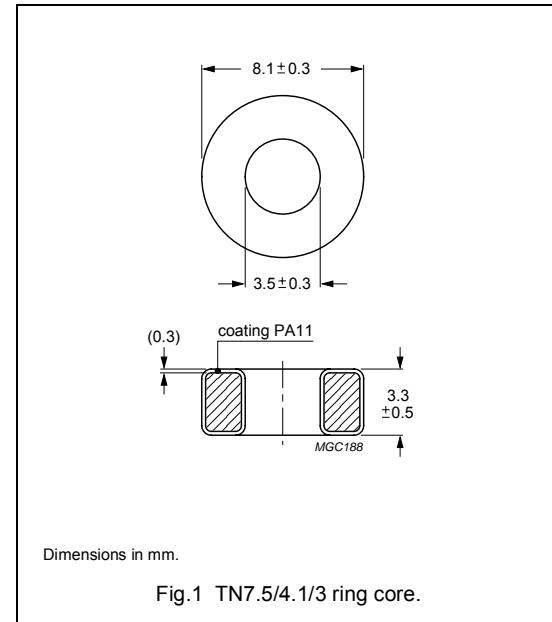

The colour is white.

Maximum operating temperature is 160 °C.

Isolation voltage

DC isolation voltage: 1500 V.

Contacts are applied on the edge of the ring core, which is also the critical point for the winding operation.
